This is by no means the language of hyperbole. For the forces which give origin and their motions to the planets, and give shape and their properties to all forms of nature, are the same whose co-operations and resultants we study in the tissues of the human body, a fact vaguely foreshadowed in the ancient union of astrology with medicine.

Apparently restricted as is the human body with which we deal, it does not limit our thoughts to its grosser mechanism. We find an abyssal depth beyond reach of the microscope below, as there is one extending infinitely beyond reach of the telescope above us. De Quincey has written that the safety of empires has been suspended, like the descent of an avalanche, upon the moment earlier, or the moment later, of a cough or sneeze. But a sneeze is a force in magnitude like an earthquake compared with that let loose by a variation in the adjustment of atoms in molecules. Diseases may decide the course of a nation's history. Yet the solution of the question concerning the germinal and chemical origin of diseases, depends upon evidence, on the one hand, from the violent reactions induced by atomic changes, as in the molecules of Koch's paratubercle, and on the other hand from microscopic bacteria, which, compared with atoms, are behemoths like the fabled monsters upon which the earth is supported. From these depths of the exceeding minute, the range of physical forces, through chemical and biological expressions leads us up to and through all phases of mental activity. There is not a department of life which medical knowledge, so called, does not penetrate to its very centre with enlightening force; even into spheres where the highest faculties of men are exercised; into mental philosophy, education, morals, age, religious faith and destiny as well.

Certainly whether the mind of the doctor shall be tasked, disciplined, enlarged with broad veins of human life in all its relations and needs, in a word liberally educated, is a question not of the range and character of the studies his profession demands; but, as in all other departments of learning, of the disposition of the student and practitioner himself.

Never has there been a time when medical men could more justly regard their calling with enthusiasm, — an enthusiasm relying not upon such haphazard methods as led the alchemists to hit upon unsought facts; nor upon lucky guesses like Swift's, who made his veracious Captain Gulliver, fresh from Lilliput announce the existence of two moons of Mars, one hundred and fifty years before they were actually discovered; but an enthusiasm springing from the natural basis, the precise methods, the trend of modern studies, according to which, fresh truths are now sought by cultivating the roots out of which they may come as natural fruit.

Let me conclude by adding, that in the alertness of members of this Society to utilize fresh discoveries, and in their disposition to hold present acquisitions

as germinal rather than as final forms of knowledge, we find a warrant for the existing spirit of expectancy, according to which steady advances are to secure to us increasing measures of medical skill. Such expectation begets a rational confidence, such confidence predetermines success.

I cannot, as did our chairman, resist the temptation to add a sentiment to the name he has uttered. Therefore, I give you: "The Massachusetts Medical Society—venerable in years, honored by her history, ever noble in her aims; may her grateful children continue to sustain her reputation as a wise promoter and conservator of medical learning."

#### THE COMMONWEALTH OF MASSACHUSETTS.

In the olden time it was Church and State; it is now Medicine and State; and the bond is strengthening year by year. We certainly extend a hearty helping hand to the Commonwealth, as we also do to its Chief Magistrate. In the absence of Governor Russell, I call upon His Honor Lieutenant-Governor Haile, to respond to this toast.

LIUT.-GOV. W. H. HAILE:—You all regret the absence of His Excellency the Governor, on this occasion. He desired me to state to you his great regret that he is unable to be here. I deem it an honor to be called upon to respond for the Commonwealth of Massachusetts. Her history is contemporaneous with the history of our common country, and we are justified, we believe, in claiming that in all those attributes which tend to elevate and strengthen humanity, in all the efforts that have been made and are being made in educational and scientific lines, and in the proper solution of the great social and moral and religious problems of the times, our Commonwealth stands foremost in the sisterhood of States. One of the elements of her true greatness is shown in the regard she has always manifested for those departments and institutions which have for their object the good of the people, and in her generous appropriations toward the maintenance of the same.

Next to the ministry, the medical profession, to my mind, is the noblest in the world. Practically, the one should be the supplement of the other. The famous maxim, "A sound mind in a sound body," will remain in force until the end of time. You are celebrating to-day the one hundredth and tenth anniversary of your Society under the most pleasant auspices. A century ago you had but thirty-one members. To-day it appears that you have nearly eighteen hundred. I congratulate you upon its present excellent condition.

I am glad personally to be here to-day to officially bring to you the hearty greetings of the Commonwealth, and to assure you of her glad recognition of the vast amount of good this Society has been the means of accomplishing, and of her good wishes for its continued prosperity.

#### THE CITY OF BOSTON.

Our fellow-citizen, Bellamy—with his wonderful faculty of seeing ahead by looking backward—has pictured Boston as it will appear one hundred and fifty years hence, and a highly interesting picture it is; but like the passage of the anthropoid ape to man, there are interesting links wanting—the first of which, the Immediate Future of the City, will now be sup-

plied, in the absence of the Mayor, by Dr. O. K. Newell, of the Board of Commissioners of Public Institutions.

DR. NEWELL, in behalf of the mayor, extended to the Society the welcome of the City of Boston and her hearty congratulations. He referred to the stand which the mayor took early in his administration as regards the cleanliness of the city's streets, and declared that His Honor would always be found in sympathy with the medical profession in all its endeavors to improve the sanitary condition of the municipality.

#### THE CITY OF NEW YORK.

New York is great in itself, in its achievements. It has a bridge that is one of the wonders of the world, and elevated railways that bid fair to equal the length of the Great Wall of China; but it has nothing more worthy of our admiration than its physicians and surgeons. We recognize their infinite ability; and are proud to greet them on this occasion, in the person of one second to none in his skill and acquisitions. I have the great pleasure to present to you Dr. D. B. St. John Roosa, of New York City.

DR. D. B. ST. JOHN ROOSA: Our Society in New York is one by delegates, and is much smaller than yours; and when we come together it cannot be said to be representative as you are. In New York we have no antagonism to the City of Boston or to the State of Massachusetts. They accuse us of having antipathies to the old State House in Philadelphia and to the medical institutions of that town, which is so near us and yet so far. But we have been compensated by the retort that a Boston man made to a Philadelphian on the exclamation of the Philadelphian that Boston was not so well laid out as Philadelphia: "No," said the Boston man, "but when Boston has been dead as long as Philadelphia it will be much better laid out." When a man, even a doctor, goes within sight of Bunker Hill, he must think of Major-General Warren, a member of this Society, or at least a regular member of the constituted profession at that time. There are very few instances in history where a medical man has been compelled to buckle on his sword, and, at the head of battalions, labor for the rights and the freedom of his country. There are one or two, and your instance, to which I have referred, is perhaps at the head.

We perhaps need to be reminded occasionally that, although we are members of the medical profession, and although our chief and general, our constant duties are to be confined to the performance of the work which is assigned to us as healers of the sick, nevertheless, according to the Lieutenant-Governor of the Commonwealth or the President of Harvard University, we are also men, with the same interest in the welfare of the State that any citizen has; men, with political and religious and other opinions. And in our own way, as we think best, we have the same right, freely given to us in this land, to impress our opinions upon our fellow-men.

Without any reflection upon the religious opinions of any man or any set of men, we account it a great felicity in our own profession, in New York at least, that we have there no orthodoxy in medicine, and consequently there can be no heresy. We have endeavored in the State of New York to solve this great problem, to prevent the denunciation of heresy, to

prevent the promulgation of unsound doctrine. Whether successful or not I cannot say; it is a matter still for public consideration and probably for public approval. We have passed a law which obliges every man who undertakes to practise medicine in that State to undergo an examination, not only from his college, not only to pass through the portals of his regular Society, whatever that may be, but also those of a Board of Medical Examiners, chosen independently by the Regents of the University of the State. I am happy to think, from the suggestion of approval of a part of you, that in the State of Massachusetts you may be willing to undertake to solve this great problem of securing the unity of the medical profession in the same way. Certainly there will be no difficulty in your minds or mine as to the character of the medical men, if we can assure ourselves that they are grounded fundamentally in anatomy, physiology, chemistry, in those exact sciences, those fundamental sciences which lie at the basis of the successful practice of the healing art.

There is another subject agitating us in New York to-day, and I understand that it is agitating you also in Massachusetts, to which I will briefly allude. I was told to-day that the judges of one of your great courts were poisoned, while sitting on the bench administering justice, by the sewer gas that was constantly escaping beneath their feet, through the total neglect of the so-called or whatever sanitary authorities there may have been in the city of Boston at that time. Whether that be true or not of your city, such instances are true of other cities. This means that in the State of New York we have been thrust out from the positions which are adequately ours, and that men educated in other sciences possibly, men possibly educated in literature, men possibly educated in politics, have been put at the head of health boards and sanitary boards of control, until the medical profession has foregone all control of the thing whatsoever and has contented itself, has been forced to content itself, with its individual responsibility in reference to each individual case.

Now, is this right? Is this just? Should the President of the Board of Health of the city of New York be a plumber? Certainly, certainly medical men, and only medical men, should control sanitary affairs. As to our success in managing such affairs when they have been given into our control, I point to the record of the medical officers of the Army and the Navy of the United States, where we had not the advantage of lay wisdom, and, thank God, of lay authority, but where we were the factors, where we were the captains. The improved hospitals of the Army of the United States, the adequate medical service on board our ships of war, they are our monuments and our triumphs, which contributed as much as did Hancock and Sheridan, to the success of our armies. We are perfectly adequate for these responsibilities, and we must impress ourselves upon our fellow-men until they accord them unto us. It is a small thing to cut off a leg; it is a great thing to prevent the necessity for cutting off one.

I will simply close by an adjuration made not to us, but perfectly appropriate to us and to our profession:

"Men, my brothers; men, the workers, ever reaping something new  
That which ye have done is but the earnest of the things that  
ye shall do."

(To be continued.)

## THE BOSTON

## Medical and Surgical Journal.

THURSDAY, JUNE 18, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

### ETIOLOGY AND TREATMENT OF CHRONIC ALCOHOLISM.

An interesting discussion of the cause and cure of inebriety has been going on in the *New York Independent*, under the form of a symposium. Manager Brenton of the Christian Home for Inebriates affirms that "Drunkenness is not a disease; is not hereditary, but a sin." More than one-half that came to the Home "neither had intemperate parents nor grandparents." Association was the cause in two-thirds of the cases, "which shows conclusively that drunkenness is a habit acquired." In 1,290 instances, the habit was acquired after coming of age and leaving the domestic fireside. Mr. Brenton quotes statistics from the Little Wanderers Home, Boston, to show that drunkenness is not hereditary. He says: "No medicine can eradicate the cravings of the victim of alcoholic beverages. It is not a disease, only the grace of God can benefit the inebriate." He very seldom invites in a physician to the Home; for the last nine months no doctor has been inside the building. He depends on faith, on prayer, on nourishing food, on kind attention and good treatment. "No man ever enters our Home in earnest but goes out saved from all his besetting sins."

Dr. L. D. Mason, of the Fort Hamilton Home for Inebriates, naturally takes a more strictly medical view of the subject. He asserts, what is indeed a physiological truism, that the underlying cause of inebriety is often heredity. In some families there is a decided tendency toward inebriety, as in other families there is a tendency to consumption or insanity. "There are men who have a bad family history in direct and collateral branches; their ancestors have suffered from insanity, drunkenness, epilepsy or some of the various diseases of unstable equilibrium of the nervous centres. When a man springing from such a family becomes an inebriate, we call him a diseased drunkard; he is a drinker from necessity, rather than from choice." The parallel between consumption and inebriety holds good: a man with consumptive tenden-

cies may by suitable hygienic precautions prevent the disease; the man with the tendency to inebriety may avoid habits that develop the appetite for alcohol. Dr. Mason in this connection makes some good remarks about the several classes that indulge in alcoholic stimulants. "A man springing from strong, robust parents, of good constitution can probably drink most of his life without suffering from the nervous, physical, or mental effects of alcohol. He is your 'single bottle' man, who drinks so much and no more; he is a systematic and not erratic drinker. Not belonging to the hereditary class, he is able to do this; but there are other men who cannot touch a glass of liquor without going on a spree."

Inebriety sometimes comes on in consequence of some of the diseases which affect the brain, like a blow on the head, a fractured skull, etc. A dipsomaniac is a man with the liquor craze; he cannot do without the intoxicant, and will sacrifice everything to get it. These men at periodical times have the irresistible impulse to drink. On the other hand, the chronic drunkard keeps himself intoxicated continually.

Beer and wine drinking, in Dr. Mason's opinion, are oftener the cause than the cure of drunkenness. Mr. Brenton says the most hopeless inebriates have been the beer drinkers.

In the treatment of inebriety, Dr. Mason favors the instant and complete withdrawal, where this can with safety be done. In the case of the broken-down, habitual drunkard, who has undermined his constitution, the "tapering-off" plan is the best. In the Fort Hamilton Home, powerful nervines and tonics are used in conjunction with a gradual withdrawal system in bad cases. Dr. Mason insists that the proper place for the victim of alcoholism is an inebriate asylum. Home treatment is a failure. The inebriate has lost his self-control; he must be placed in some institution where for a certain period, varying from six months to a year, he can be under intelligent medical supervision. He will be treated by the various means that go to build up the nervous system—tonics, massage, a liberal diet, and cheerful surroundings. His system must be toned up to a good average normal standard. After that, he may be allowed a little liberty outside the institution. If he stands the test, he may be gradually restored to his friends and society.

"Taking all classes of inebriates," says Dr. Mason, "we cure forty-five per cent., which is a pretty good showing. When people recognize that the best way to cure the inebriate is to send him to the asylum, we will probably cure sixty to seventy per cent. of such cases because they will then be sent to us early enough to effect a cure."

Justice James T. Kilbreth writes that the chronic drinking habit among the poor "is to be attributed to laziness, idleness, and to a very large extent, to the absence of the social comforts and agreeable surroundings which are enjoyed by persons in better cir-

cumstances." The tenement-house system, he thinks, is responsible for a great deal of drunkenness; and unhappiness in domestic life has much to do with making drunkards of men. It is largely due "to the lack of social opportunities" that laboring men frequent the beer saloon or the liquor saloon, which is the poor man's club.

Mr. Perry, pharmacist, says: "The excessive strain of work we are under in this modern age is the primary cause, in most cases, of the use and abuse of stimulants. For instance, take physicians. Many a sick call at night would never have been made by a doctor when he has been worn out with his day's labor, if it had not been for the use of a stimulant to brace him up for the extra and unexpected exertion. He really feels worn out, too tired to make another call, but here is one of his best patients who demands that he shall attend him. The consequence is, he takes a drink of whiskey, and obeys the summons. Lawyers get worn out over their work and pursue the same practice, and the same may be said of journalists whose work is particularly arduous, is often done at night, and in a great hurry."

Dr. Charles L. Dana writes about the treatment of bad cases of drunkenness at Bellevue: "The patients when they first come in are given a cathartic and ordered a diet of milk and beef tea. If they reject food, they are given powders of bismuth and capsicum or rhubarb and soda. Alcohol is at once stopped, unless there are complications, as pneumonia. In treating some inebriates, the rule is to allow them to 'taper-off' gradually, this being considered the safer plan. At Bellevue, however, we cut the drink off short, unless the patient is in very bad shape indeed. In the milder cases, they are put upon a mixture of bromide and chloral, with sometimes paraldehyde, taken every two hours till sleep ensues. If this treatment is not effective, a hypodermic of morphine and amorphous hyoseyamine is given and this is usually sufficient. . . . Despite all that can be done, the patient will sometimes not sleep, or if he does, the sleep is only a narcotism, from which he awakes without being refreshed; the delirium continues, and death from exhaustion follows."

Dr. Albert Day, in the thirty-third annual report of the Washingtonian Home of Boston, lately published, speaks of intemperance as a "disease," and says: "We cannot come to any other conclusion, when we individualize upon the subject, than that every habitual drunkard should be regarded as a monomaniac, and that he should be treated as an insane man, both in law and in fact, according to the humane and enlightened principles which prevail at this day in the department of medical ethics and jurisprudence."

PROBABLE FOUR-YEARS' COURSE AT THE JEFFERSON MEDICAL COLLEGE.—The trustees of the Jefferson Medical College in Philadelphia have under consideration the project of establishing a four-years' course.

# A COLLEGE COURSE FOR STUDENTS OF MEDICINE.

THE Illinois State Board of Health has issued a circular, under date of the 6th inst., urging upon colleges throughout the country the establishment of a course suitable for young men intending to pursue the study of medicine after graduation. The Board feels that there is a demand for such a course, recognizes that it has been met by a few of the "literary institutions" in the United States, and hopes and believes that it will be still more generally provided for in the course of the next two years.

Among the "institutions" which now offer science courses for students who intend to study medicine, or who intend to teach or otherwise engage in biological work, it enumerates the following: (1) University of Wisconsin, (2) University of Pennsylvania, (3) Johns Hopkins University, (4) University of Notre Dame, (5) Yale University, (6) Cornell University, (7) Princeton University, (8) Lake Forest University, (9) North-Western University, (10) West Virginia University, (11) University of Kansas.

Of course, there are other admirable institutions of learning, such as the Massachusetts Institute of Technology, which we suppose the Board does not regard strictly speaking as "literary institutions," which offer such courses.

In the estimation of the Illinois Board such a course should be based on biology, and should include thorough work in this science as well as in osteology, comparative anatomy and chemistry, physics, with English, French, German, Latin, clay modelling, free-hand drawing, mineralogy, mathematics through trigonometry, mechanics, logic, general and pharmaceutical botany, and (in the last year) psychology.

The aid and advice of medical faculties, and of teachers interested in the subject, is requested by the Board in making up the schedule of such a "science" course as can be recommended to any college wishing to adopt one which shall extend over four years and shall be at once practical and instructive.

This Board of Health, as is well known, is also charged with the administration of the law for the regulation of the practice of medicine in Illinois. It now requires that students of medicine matriculating in the autumn of 1891 or thereafter must study medicine four years and must attend three courses of lectures,—no two in the same twelve-month,—in order to obtain a licence to practise in Illinois; a rule which, it is expected, will apply also in some other States. The Board, however, proposes to recognize a thorough course in science, such as that outlined above, as equivalent to two years' study and one course of lectures, thus enabling the student to enter the second class in the medical college, and making "the full time of study six years in the literary and medical schools, or two years less than is required of the student pursuing a strictly classical course. Not only will time be thus saved, but the science student will be much better

prepared to enter the second course of the medical school than will the classical student be to enter the first year."

## MEDICAL NOTES.

**COMPULSORY MEDICAL EXAMINATIONS.**—The *New York Medical Journal* says that the question of the power of a court to order a medical examination of the person by a designated examiner has been decided in the negative by the United States Supreme Court, on an appeal in the case of a suit for damages for personal injuries brought by a lady against one of the great railway corporations. Two of the judges dissented, but it may be taken for granted that the decision mentioned is final. The absolute sanctity of the person, except in criminal cases, seems to admit of no question.

**MEDICO-LEGAL SOCIETY OF CHICAGO.**—At the annual meeting held at the Grand Pacific Hotel, June 6th, Judge O. H. Horton was unanimously elected President for the coming year; Dr. D. R. Brower, Vice-President; Dr. James Barry, Second Vice-President; Dr. Joseph Matteson, Treasurer; Dr. Archibald Church, Secretary. Drs. Henry M. Lyman, W. Franklin Coleman, A. Holmboe, and L. T. Potter were elected to active membership.

**LEPER COLONY IN BRITISH COLUMBIA.**—An isolation of all lepers found at large in the towns of British Columbia has been ordained by the Dominion government. An island off the coast, called Darcy's Island, has been set apart, and will immediately be prepared for the reception of the leper colony, composed chiefly of Chinese.

**AN ETHNOLOGICAL CONGRESS** will be held in Paris in September, 1892, in connection with which there will be an exhibition of living specimens of the different races of mankind. Several well-known explorers have undertaken to do their best to make the collection of "specimens" as complete as possible.

**HONORS TO DR. LASSAR.**—The French Government has conferred the Order of the Legion of Honor on Dr. O. Lassar, General Secretary of the Tenth International Medical Congress, held at Berlin in August, 1890, in recognition of his "great and successful labors" in the organization of the meeting.

**INFLUENZA.**—It will undoubtedly take some time before the extent of epidemic influenza during the first months of this year is accurately known. It is reported to have swept through China in a very severe form in February, and caused a very large mortality. In London, during the week ending May 16th, the number of deaths referred directly to the disease was 266, a number double that of any week in 1890. At about the same time, Paris was free from it; but it prevailed to an alarming extent in a few towns in Alsace, Egypt, and in Russia. It was very prevalent in Norway.

The Indians of Alaska are reported to have died during May to an alarming extent. A peculiar feature of the epidemic this year appears to be that while it is reported from different parts of the world at about the same time, cities very near each other are very differently affected, both in the time and especially in the violence of the epidemic, as shown by the increased death-rates. In Gibraltar, the authorities have declared that influenza shall be comprised among the diseases defined as infectious or contagious, and have quarantined vessels having it on board. Among the vessels quarantined was the British man-of-war *Thunderer*, a large part of the crew being affected.

**WESTWARD THE COURSE, ETC.**—The following has been received, dated May 28th. "By invitation, a number of the leading physicians of Leadville, Col., assembled at the Sisters' Hospital for the purpose of witnessing the first administration of Koch's lymph in Leadville. The subject of the experiment was Mike Ford, who was sent to the hospital from the jail a few days ago, who, the doctors say, has a well-defined case of tuberculosis. The doctor who was conducting the experiment, poured a few drops of distilled water and a tenth of a milligramme of the lymph into a shallow vessel. This was taken up into a hypodermic syringe, and the wicked little needle was jabbed into the pit of the stomach, and the precious fluid introduced into Mr. Ford's circulation. He said after the first insertion that he felt much better. The doctor was at the hospital again at six o'clock, and found the patient in a chill, which, he stated, was a very favorable indication. Two hours later Ford's pulse was eighty-five, and his temperature had reached the 101 notch."

#### BOSTON AND NEW ENGLAND.

**BOSTON CITY HOSPITAL CLUB.**—The third annual meeting and dinner of the club was held at the Hotel Thorndike, on June 9th. The following officers were elected: President, Dr. Oliver F. Wadsworth; Vice-President, Dr. J. F. A. Adams, of Pittsfield; Secretary, Dr. Rufus A. Kingman; Treasurer, Dr. Silas H. Ayer.

**WARNING TO MASTERS OF VESSELS.**—The Boston Board of Health issues the following information for the benefit of masters of vessels: Within the past week two vessels having measles on board have passed our quarantine without stopping for inspection, their masters laboring under the impression that some inspection would take place up at the city, which would excuse the regular inspection in the harbor. Masters of vessels are reminded that the permanent quarantine regulation at this port, made, published and in operation for many years, forbids the bringing up to the city of any vessel with sickness of a contagious or infectious character on board, or such vessel leaving quarantine without the written permit of the port physician. This regulation is still in force and no further excuses for ignorance or delusion will be accepted by the Board of Health.

**HARVARD SUMMER COURSE IN PHYSICAL TRAINING.**—The course opens this year on June 29th, in the Hemenway Gymnasium, and lasts five weeks. Almost the whole of each day is occupied, from 9 until 11 there being lectures, 11 to 1 classes in short exercises, and in the afternoon lectures and exercises. Dr. D. A. Sargent will be in charge of all divisions. The lectures and lecturers as at present announced are—Dr. Henry P. Bowditch, "Composite Photographs," and "The Growth of Children;" Dr. Clarence J. Blake, "Testing the Hearing;" Dr. Walter Channing, "Influence of Exercise on the Nervous System;" Dr. Thomas Dwight, "Anatomical Peculiarities of the Human Skeleton;" Dr. George W. Fitz, "Elementary Anatomy and Physiology;" Dr. Charles L. Scudder, "Spinal Curvature;" Dr. J. Gardner Smith, "Physical Diagnosis and Exercise as a Therapeutic Agent;" Dr. Myles Standish, "Testing the Sight;" Dr. Duren J. H. Ward, "Anthropology;" Dr. Samuel G. Webber, "Massage and its Applications."

**MAINE MEDICAL ASSOCIATION.**—The thirty-ninth annual meeting was held in Portland, June 9th, 10th and 11th. The annual oration was delivered by S. C. Gordon, M.D., of Portland, on "Common Sense in Medicine." Officers were elected as follows for the ensuing year: President, Dr. Edwin M. Fuller, of Bath; First Vice-President, Dr. Bigelow T. Sanborn, of Augusta; Second Vice-President, Dr. George A. Phillips, of Ellsworth; Recording Secretary, Dr. C. D. Smith, Portland; Corresponding Secretary, Dr. C. E. Williams, of Auburn; Orator, Dr. J. L. M. Willis, of Elliot. The next meeting will be held in Portland, beginning on the second Wednesday in June, 1892.

**RHODE ISLAND MEDICAL SOCIETY.**—The eightieth annual meeting was held in Providence, June 11th. The annual address was delivered by Dr. Francis Minot, of Boston. The report of the secretary showed that at the last meeting there were 206 members, with an addition of 18 new fellows. Nine have since died and one resigned, thus leaving 214 on the roll. The officers elected for the ensuing year were: President, Dr. William H. Palmer, of Providence; First Vice-President, Dr. Robert F. Noyes, of Providence; Second Vice-President, Dr. E. P. Clark, of Hope Valley; Secretary, Dr. William R. White, of Providence; Treasurer, Dr. George L. Collins, of Providence.

#### NEW YORK.

**COLUMBIA COLLEGE COMMENCEMENT.**—The one hundred and thirty-seventh Annual Commencement of Columbia College, including its Medical Department, the College of Physicians and Surgeons, was held in the new Music Hall on Fifty-seventh Street, on the evening of June 10th. There were one hundred and thirty graduates in medicine, and in speaking of the recent consolidation with Columbia of the New York College of Physicians and Surgeons, President Low said in his Address: "A moment's reflection will satisfy every one how full of significance for medical education in this country is this happily

consummated union of the College of Physicians and Surgeons with Columbia College. None perceive this more clearly than the Medical Faculty, and to no one is so much praise due for bringing it about as to Dr. James W. McLaue, the honored President of the College of Physicians and Surgeons."

**THE WILL OF DR. FORDYCE BARKER.**—By the will of the late Dr. Fordyce Barker, the New York Academy of Medicine is to receive all the works in his library relating to obstetrics, gynecology and the diseases of children.

## Miscellany.

### THE RESULTS OF THE REMOVAL OF THE UTERINE APPENDAGES.

DR. KEPPLER, at the Tenth International Medical Congress, gave the after history of eighteen cases, which he had followed up and carefully studied.<sup>1</sup> In each of the patients the operation had been done for gross diseases of the sexual organs, such as pyosalpinx, salpingitis, oöphoritis, uterine myoma — and never for psychosis or neurosis. Both tubes and ovaries were always removed. The therapeutic effects were good, the patients in all cases being relieved of their symptoms.

The anatomico-physiological results were likewise uniformly good:—In no case did a typical menstrual hæmorrhage occur after the operation. The countenances of the women remarkably changed, and the women became quieter and more beautiful(!). In all cases the conjugate diameter of the pelvis became shorter, this effect being more pronounced in the younger patients; the shortening amounted to two to three centimetres. The vagina became shorter and narrower, the mucosa thinner, smoother and paler. The cervix became shorter, the uterus smaller, the introitus vaginæ narrower. The breasts became smaller and the nipples paler. The tendency to become stouter which has been described by other operators was not observed in any case. The sexual instinct was always preserved. Three patients, virginal before operation, married later and lived in happy wedlock. The passions persisted, particularly when the operation was performed early on young persons. In myoma the results of the operation were good both as regards the hæmorrhage and the shrinking of the tumor.

### PRESCRIPTIONS.

**GONORRHOËAL RHEUMATISM.**—Where other means have failed, Rifat has obtained good results from phenacetin.<sup>2</sup> He begins with fifteen grains three times a day, and slowly increases the dose, if necessary, to forty grains.

**GALLGA OFFICINALIS AS A GALACTAGOGUE.**—Dr. Curiel de la Carrère<sup>3</sup> has obtained results from the use of galega, which lead him to hope for its restoration to therapeutic use. He used the aqueous extract (equal to one-fifth of the weight of the dry plant), making it from the fresh plant. The extract has a

pronounced odor, is very soluble in water, is incompletely so in alcohol, and is given in quantities of one to four grammes daily, in fractional doses of fifty centigrammes to one gramme.

**GLYCERINE JELLIES FOR THE HANDS.**—The *Chemist and Druggist* gives the following formulas:

R	Tragacanth . . . . .	3 i.
	Glycerine . . . . .	3 ij.
	Water . . . . .	3 iv.
	Extract of rose . . . . .	gtts. vi. M.
R	Gelatin . . . . .	3 ij.
	Glucose . . . . .	3 i.
	Glycerine . . . . .	3 vi.
	Water . . . . .	3 ij.
	Oil of rose . . . . .	gtts. v. M.

**SALICYLATE OF SODIUM FOR CORYZA.**—The *Journal de Médecine de Paris* gives the following:

R	Salicylate of sodium . . . . .	aa 3 ss.
	Syrup of orange . . . . .	3 vi. M.
	Peppermint water . . . . .	3 vi. M.

At the onset of the attack a teaspoonful to a dessert-spoonful should be given every three or four hours.

**CREOLIN IN TONSILLITIS.**—Following up Leyden's recommendation of creolin as a disinfectant for the throat, Dr. Itzig<sup>4</sup> has used it in follicular tonsillitis with marked success. Under its influence the purulent plugs in the lacunæ, as well as the swelling, tenderness and fever, disappeared within twenty-four hours, and the patient rapidly recovered. It was prescribed as a 1 per cent. solution, diluted with equal parts or more of warm water; and was used in the form of a gargle several times daily. The disagreeable burning feeling in the throat, which creolin causes, disappears rapidly on washing out the mouth with pure warm water.

## Correspondence.

### AN OPEN LETTER TO PROF. ROBERT KOCH OF BERLIN.

NEW YORK, June, 1891.

DEAR DOCTOR:—In common with many others, I sincerely regret that treatment of tuberculosis by your method and your remedy has been almost universally discredited. This is the more to be deplored as there can be no doubt that you were and are now on the right track. If in the wholesale condemnation the pendulum has swung too far the other way, it may not be out of place to inquire into the reasons therefor. This can be readily and conveniently done under three headings:

(1) How much is the general profession at fault in this matter?

Before outlining a plan of treatment for any disease, it is necessary to have a clear picture of the pathological condition before you on the one hand and the patient's resisting power on the other. This is especially true of the manifold chronic lesions of the lung known under the convenient but very inappropriate name of phthisis pulmonalis. The *sine qua non* in this complex of conditions is an *exact and discriminating diagnosis*. It goes without saying that not one in a hundred medical men are capable of making such a diagnosis. But let me not be understood as saying that wholesale mistakes in physical diagnosis occur in this country alone.

\* Therap. Monatshefte, No. 9, 1890.

<sup>1</sup> Birmingham Medical Review, June.

<sup>2</sup> Fortsch. der klinisch-ther., May, 1891.

<sup>3</sup> Jour. de Méd., April.

In a country like Germany where, notwithstanding the exhaustive labors of Prof. James R. Leaming of New York and Sir Andrew Clark of London, the existence and importance of chronic and progressive pleuritic adhesions without other complications, but with far-reaching effects on account of mechanical hindrance to respiration, is practically ignored; in a country where pretubercular conditions, infiltrations as yet non-tubercular, and similar lesions, are allied under the heading of "tuberculosis" (*Die Tuberculose*)—an exact picture of the existing lung condition is quite as frequently marred as it is in this country; and you will pardon me for mentioning in this connection the well-known fact that the overweening self-esteem of some German authorities still finds expression in the ancient saying, "What good can come out of Nazareth?"

Not only suffering mankind, but your great discovery, would have fared better, had you adhered for a year or two to your original resolve to keep the whole matter a secret. And when the use of your lymph comes to the front again, as I feel confident it will, let every one who imagines himself competent to apply it, first undergo a severe examination in physical diagnosis of the lungs and as to his natural sense of hearing—his more or less musical ear in particular.

(2) How much are the remedy and the method itself at fault?

The answer to this question is partly included in the above paragraph: Indiscriminate diagnoses and still more indiscriminate use of the remedy, particularly in your country. You will say that this is not the fault of either the remedy or the method. To this I answer: If the exact conditions for the use of the remedy had been more closely studied and outlined, and the dosage and interval of administration sharply defined, much mischief and confusion would have been avoided. And, above all things, the whole matter ought to have been kept out of the daily newspapers. This, I feel assured, was not your individual fault.

Tuberculin may be defined as a product of matter—metamorphosis (*Stoffwechselprodukt*), diluted and conserved by fifty per cent. of glycerine. It is a toxalbumin of intense virulence, and contains, besides a certain percentage of the active principle tuberculin, mineral salts, coloring and extractive matter, originating from the nutritive ground. Before this letter is published, the tuberculin solution may be freed from these admixtures, since Professor Klebs has already succeeded in doing so. The original solution, which has been so widely condemned, contains, as I understand it, all of the above products of disintegration (*Zersetzungsprodukte*) and it is fair to assume that to these, were due in a great measure the distressing general symptoms observed. To my mind, this is no evidence against the value of tuberculin itself. It merely proves that the threatening symptoms produced by these extraneous matters overtopped the action of the specific remedy, and clouded the whole picture. Right here, I beg of you not to consider me arrogant, if I now propound the third question:

(3) How much were you at fault?

Taking the inoculation of successively attenuated cow-pox virus as a guide, you conceived the brilliant idea of introducing into the human system a material *formed outside of the body* in the shape of successive attenuations of the tubercle bacillus, to insure immunity against future invasions of the microbe. In other

words, the lymph influences the blood in such a manner that in case of a future invasion of bacilli they will find no favorable soil for their growth, and hence perish.

The next step was the inoculation of lymph into a body already invaded by an infectious disease. As I understand it, the inoculation of tuberculin in this connection aims at giving rise to a process by which further proliferation of bacteria already lodged in the system is to be prevented, and the human organism enabled to successfully cope with the chemical virus generated by them. Notwithstanding your frequent explanation to the effect that saturating the system with tuberculin would tend to deprive the bacilli of their nutritive soil and give the organism a chance to cast off tissue made necrotic by bacillary products, there appears to be a fixed impression in the minds of medical men that you were aiming a direct blow at the life of the bacillus itself. In other words, they believe you intended to find a *specific*—a bacillus killer, so to speak. It may be you have not been quite explicit enough on these points.

Three points appear to be fairly well established:

(1) That neutralizing, drowning, of the bacillary chemical product—depriving the bacilli of their nutritive soil—is the therapy of the future.

(2) That animal virus and intense chemical poisons are the remedies by which we may hope to accomplish this object, the more as these agencies are the most destructive elements next to fire; and the chances are that animal virus pitted against a chemical substance within the body acts more powerfully than when one chemical is made to antagonize another.

(3) That diffusion throughout the system can only be secured by the hypodermic method.

I trust you will not take it amiss if I suggest that your only fault lies in your absolute belief in one particular virus only—a product of animal life—instead of allowing that in certain cases tuberculin (freed of extraneous matter); in others, cantharidin; again in others, the lymph of cow-pox, as used by myself, will accomplish the desired object. Your virus, however, may prove to be the most powerful of any present or future series of animal poisons.

Very respectfully yours,

J. HILGARD TYNDALE, M.D.

#### METEOROLOGICAL RECORD,

For the week ending June 6, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,985; under five years of age 1,106; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 501, acute lung diseases 406, consumption 354, diphtheria and croup 24, typhoid fever 102, diarrhoeal diseases 94, scarlet fever 75, measles 32, whooping-cough 27, cerebrospinal meningitis 24, erysipelas 10, puerperal fever 9, malarial fever 3.

From scarlet fever New York 33, Brooklyn 14, Philadelphia 8, Chicago 7, Milwaukee 4, Cincinnati 2, Boston, Baltimore, Cleveland, Springfield and Chelsea 1 each. From measles New York 15, Chicago 6, Brooklyn 1, Philadelphia, Washington, Nashville, Charleston, Portland, Lynn and Waltham 1 each. From whooping-cough New York 7, Chicago and Philadelphia 6 each, Milwaukee 3, Brooklyn and Baltimore 2 each, Cambridge 1. From cerebro-spinal meningitis Chicago 15, New York 1 each, Brooklyn 3 each, Baltimore, Washington and Lynn 1 each. From erysipelas New York and Brooklyn 4 each, Chicago and Salem 1 each. From puerperal fever Chicago 6, Cleveland 2, Boston 1. From malarial fever Brooklyn, Baltimore and Nashville 1 each.

**OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 6, 1891, TO JUNE 12, 1891.**

By direction of the Secretary of War, the leave of absence, on surgeon's certificate of disability, granted Major SAMUEL M. BORTON, surgeon, in Special Orders 42, March 4, 1891, from this office, is extended three months, on surgeon's certificate of disability. S. O. 129, Par. 6, A. G. O., June 1, 1891.

With the approval of the Acting Secretary of War, leave of absence for fifteen days, to take effect on being relieved from duty at Fort McHenry, Md., is granted Major CHARLES B. BYRNE, surgeon. S. O. 130, Par. 14, A. G. O., June 8, 1891.

The leave of absence for seven days granted Major PHILIP F. HAYES, surgeon, by Orders No. 96, current series, Fort Keogh, Mont., is extended forty-four days. S. O. 138, Par. 2, Department of Dakota, June 5, 1891.

The leave of absence for seven days granted First Lieutenant FREDERICK V. WALKER, assistant surgeon, U. S. Army, by Orders No. 100, current series, Fort A. A. Russell, Wyo., is extended twenty-three days. S. O. 138, Par. 6, Department of the Plate, June 5, 1891.

By direction of the Acting Secretary of War, Lieutenant-Colonel CHARLES T. ALEXANDER, surgeon, attending surgeon in New York City, is, in addition to his other duties, assigned to duty as examiner of recruits in that city. S. O. 132, Par. 21, A. G. O., June 10, 1891.

**OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 13, 1891.**

A. R. ALFRED, assistant surgeon, from Naval Hospital, Norfolk, and to the "Fenn."

JAMES STOUTON, assistant surgeon, to duty Naval Hospital, Norfolk, Va.

L. L. S. YOUNG, assistant surgeon, to duty at Naval Station, Fort Royal, S. C.

A. A. HOCHLING, medical inspector, ordered as member Naval Medical Examining Board.

T. H. STREETS, surgeon, ordered to duty on the U. S. S. "Bennington."

P. S. WAILES, medical director, ordered as delegate to represent Medical Corps of Navy to the International Congress of Hygiene and Demography at London, Eng.

**VIRCHOW TESTIMONIAL FUND.**

The Boston members of the American Committee have received the following contributions:

Amount previously acknowledged	\$610.00
Through Alfred L. Loonis, New York	469.00
John G. Blake, Boston	10.00
David W. Cheever, Boston	10.00
George H. Lyman, Boston	10.00
Samuel W. Fletcher, Pepperell	5.00
Frederic W. Chapin, Springfield	5.00
George K. Sabine, Brookline	5.00

**APPOINTMENT.**

Dr. O. F. Wadsworth has been appointed Professor of Ophthalmology in the Harvard Medical School.

**DEATHS.**

F. N. WHEELER, M.D., of Camden, Me., died June 13th.

THOMAS P. GARY, M.D., President of the Florida Medical Association, died in Ocala, Fla., June 10th, aged fifty-six.

ROBERT MARTIN, M.D., F.R.C.P., Consulting Physician to St. Bartholomew's Hospital, died in London, May 13th, aged sixty-three.

**BOOKS AND PAMPHLETS RECEIVED.**

A Text-Book of Chemical Physiology and Pathology. By W. D. Haliburton, M.D., F.R.C.P. Illustrated. London: Longmans, Green & Co. 1891.

Report of Committee on Pathological Anatomy, Parenchymatous Aspiration: A New Method of Diagnosis. By Albert Abrams, M.D. San Francisco.

The Steps of the Cesarean Section: The Do's and the Don't's. By Howard A. Kelly, M.D., Professor in Gynecology to the Johns Hopkins University. New York: William Wood & Co. 1891.

The First and Second Annual Reports of the Memorial Hospital and Washburn Free Dispensary, Worcester, Mass., from June, 1888, to December, 1890, together with the Will of the Late Hon. Ichabod Washburn.

The Microscopical Anatomy of the Human Heart, showing the Existence of Capillaries within the Muscular Fibres. By Arthur V. Meigs, M.D., Physician to the Pennsylvania and Children's Hospitals. Reprint. 1891.

The Pocket Materia Medica and Therapeutics: A Résumé of the Action and Doses of all Official and Non-official Drugs now in Common Use. By C. Henri Leonard, A.M., M.D. Detroit: The Illustrated Medical Journal Company. 1891.

## Address.

IDEALS OF MEDICAL EDUCATION.<sup>1</sup>

BY JOHN S. BILLINGS, M.D.,  
*Surgeon in the United States Army.*

WHEN the medical faculty of an ancient, famous, and progressive university honors a physician by the request that he will deliver an address to it, and to its friends, upon such an occasion as this, the subject of that address must be sought within certain limits. It should have some relation to the special work of the Faculty—to medical education as it was, or is, or should be. The fact that you have already had three addresses bearing on this subject by distinguished medical teachers, who are more familiar with its practical bearings and needs than I can be, does not authorize me to try another field, although it greatly increases my difficulty in selecting reflections and suggestions which are suited to the occasion and to the audience, and which, at the same time, will not be a wearisome repetition of what is already familiar to you. I know, however, that discourses of this kind are soon forgotten; were it otherwise, this would indeed be a hard world for address givers.

Of course the Medical Department of Yale is organized in the best possible manner, and is doing the best possible work,—under the circumstances. I do not know precisely what its organization is, or what work it is doing, or the exact circumstances which govern it, but I have no doubt it is safe to assume this. There is one circumstance, however, which very commonly affects medical schools and universities—and which, therefore, may possibly affect you—and that is the want of means to do everything that anybody may consider desirable. Perhaps, then, some remarks upon certain modern ideals of medical education, and upon first class medical schools and their cost, based upon data derived from other schools, may be of some interest—especially in the light of Roucheffoucauld's aphorism that there is something in the misfortunes of our best friends which is not displeasing to us.

The great mass of the public—the majority of the voters of all parties, and of the women who are not voters—know little and care less about the details of professional education, or about the standard of qualification attained to by those to whom they entrust more or less of the care of their souls, their property or their bodies. The popular feeling is that in a free country every one should have the right to follow any occupation he likes, and employ for any purpose any one whom he selects, and that each party must take the consequences.

It is noteworthy, however, that each individual professing to hold this opinion, almost always makes an exception to his own occupation if it is one involving skilled labor—he is in favor of free trade in the abstract—and of limitations with regards to his own particular trade, either as to number of apprentices, as to time of study, or as to some form of trust which will prevent, as far as possible, competition in that special business. In one of its aspects, medicine is a trade, carried on for the purpose of making money in order to support the physician and his family, and to the majority of practitioners this is a very important aspect, although to very few of them is it the only

one. Hence it is that medical faculties must consider schemes of medical education from this point of view also, not exclusively so by any means, but, nevertheless, with reference to the questions: What do we propose to offer?—how much will it cost us?—how much shall we charge for it? With reference to the first question, it is obvious that there are several quite different kinds of education which a medical faculty may offer to its students. It is by no means easy to decide as to the quality and quantity of the article offered by consulting only the advertisements, circulars, and prospectuses of the one hundred and more medical schools in the United States, but even from these it can be seen that one can get a diploma of Doctor of Medicine in much less time, and at much less expense, from some schools than from others, and we all know that the diplomas of these different schools are guarantees of very different education and qualifications.

There are also several different ideals as to what is desirable in medical education. For instance, there is the ideal of the literary man, of the clergyman, of the laborer, and of other classes of the general public. There is the ideal of the man who wants to obtain a medical degree as soon and as cheaply as possible in order that he may commence practice; the ideal of the same man after he has obtained such a degree and has been for two or three years trying to get practice; and the ideal of the middle-aged successful practitioner who has learned several things by experience since he graduated. Then we have the ideal of the army and navy examining boards, the ideal of the man of means who wants to become a specialist without ever going into general practice, and the ideal of the man who wishes to be an investigator and a teacher either from the love of science or from the desire for fame. Let us consider some of these ideals briefly. The chief demand of the great mass of the non-professional public is for general practitioners, and the qualifications which these should possess may be summed up in the statement that they should be competent to recognize the forms of disease and injury which are common in the community in which they practice, and should know, and be able to apply, the remedies which are most frequently used and found efficacious in such cases. They are expected, for the most part, to follow and not to lead—it is not necessary that they should be skilled in the refinements of modern pathology—or be thoroughly trained in minute anatomy or experimental physiology, or be great surgeons, or be well up in all the specialties. Observe that I say it is not necessary, it may be desirable, but in the majority of cases it is not practicable.

In their brief journey of life through this world, the great majority of people must travel on the routes and by the vehicles provided for them by others, and, fortunately, they are usually content to do so. They move in groups which are "personally conducted," see the things they are told to see, try, with more or less success, to admire the things which they are told to admire, and their chief discomfort occurs when their conductors are either silent, or give contradictory orders, when it comes to the parting of the ways. Most travellers on an Atlantic steamer accept without murmuring the elict that "Passengers are not allowed on the bridge."

The information which those who propose to earn their living by the general practice of medicine stand

<sup>1</sup> Address delivered before the Medical Faculty of Yale College, June 23, 1891.

most in need of, is that which will enable them to recognize the ordinary emergencies of practice and to deal with them in the ordinary way. As students, their time, money, and zeal for study and investigation, are all usually more or less limited, and there are many things in a course in what is called the "higher medical education" which are of comparatively little use to them. The clinical instruction which they can get at a school in the region of country in which they intend to practise will often be more valuable to them than that which they could get at a distant school of greater repute, simply from the difference in the class of cases presenting themselves for treatment. Good local pilots are in demand, although we have a Superintendent of the Coast Survey. In some respects, the old-fashioned system of medical apprenticeships, in which the student spent from one to three years in the office of a physician in general practice before he went to a medical school to hear lectures, was a good one for producing these general practitioners.

To learn to do such work easily and properly, one must live among the sick, learn how they look, how they talk, how they are to be talked to and handled; and must do this at close quarters, and not by looking on from the top bench of an amphitheatre, or from the outer ring of a group of thirty or forty men standing around a bed. Moreover, it is the common everyday ailments and their effects and treatment that the student wants to become familiar with at first, rather than the rare cases. Cases of colic, of effects of over-eating or drinking, of sore throats, croup or diphtheria, or scarlet fever or mumps, of the ordinary fevers, of simple fractures and dislocations, of bad cuts of the palm of the hand, are far more important to him from a business point-of-view than brain tumors or ligations of the innominate artery.

And these comparatively simple, every-day cases are just what the young man reading in the office of his preceptor may become familiar with. How many of the men without such experience, who graduate this year at our great medical schools, have ever seen closely a case of measles, or scarlet-fever, or incipient small pox — or have actually looked into the throat of a child suffering from diphtheria, or have ever assisted in adjusting and dressing a fractured thigh-bone, or in getting the clothing off from a case of extensive burn or scald? I have no doubt most of them could repeat the description of these things which they have heard or read, but they are not as well prepared to deal with such cases in that unhesitating way which commands confidence, as is the man who has seen and touched one or two such cases in his preceptor's office, and has observed what that preceptor said and did.

On the other hand, the number of practising physicians who are qualified to act as preceptors, and who are willing to give the requisite time and attention to students, is very limited — and with any other kind of preceptor the student wastes much time, is apt to lose interest and become idle and unfit for continuous mental interest. If the student spent his apprentice year, or two years, in a preceptor's office either at the end of his first or second years' medical lectures, or after obtaining his degree, it would be much better for him, but the latter course is open to the objection that he would probably think that he knew more than his preceptor. The Scotch medical schools prefer that the year spent as an attached pupil shall come after

the first two years of education in a medical school. The decision of the British Medical Council has been that a five years' course of study shall be compulsory, and that the last year shall be spent in practical work.

Theoretically, there is still a considerable amount of preliminary reading with a preceptor done in this country, but practically this method of beginning the study of medicine is fast disappearing. Through the kindness of the officers of some of our large medical schools I have obtained some data on this point from which I infer that in the Eastern schools the proportion of students who claim to have read with a preceptor for one year before commencing lectures is from 15 to 30 per cent., and in Western and Southern schools from 25 to 60 per cent., but no doubt such reading in the majority of cases was merely nominal, and the student had seen little or nothing of practice. In most schools the certificate of the preceptor is not required.

The ideal of the average student who is in a hurry to begin practice needs no special description. What he wants is to pass the examinations with the least possible labor, — the less he is compelled to take for his money the better he is pleased. The ideal of the majority of the medical profession as to what should be the minimum course of study for the degree of Doctor of Medicine appears to be that the student should first obtain at least such a preliminary education as is furnished by our ordinary high schools, and then should study medicine four years, the first of which may be with a preceptor, and three of which are to be occupied in attending a graded course of lectures, the last two years being largely devoted to clinical and hospital instruction. About one-third of our medical schools have expressed their intention of carrying out this programme. As regards the time, it is not sufficient, according to European standards, but is perhaps the best general standard which can be fixed at present for the education of the general practitioner for this country. Its success depends upon whether the student has had the needed preliminary education. It is the want of this last which is the chief deficiency.

The ideal of the Army and Navy Examining Boards is that a surgeon in the Government service should have received either the literary, classical and mathematical training of the ordinary college course for the degree of Bachelor of Arts, or the training leading to a degree in scientific studies — and that after that he should have spent five years in medical studies, the last year as resident in a hospital.

This ideal cannot yet be enforced in either service, for the reason that they could not get enough men who come up to this standard to fill the vacancies, so that the actual standard is somewhat lower than this, although it is higher than the minimum standard of any medical school or of any State Board of Examiners. Through the courtesy of the surgeon-generals of the Army and Navy, I am able to give you the following results of the work of their Examining Boards for the last ten years:

Before the Army Boards, 348 candidates presented themselves during this period, of whom 76, or 22.3 per cent., were approved and passed; 31 were rejected for physical disqualifications; 90 failed to pass the preliminary examination; and the remainder failed to pass the medical examination. The rejections for physical defects are for the last three years only.

Before the Navy Boards, 237 candidates presented

themselves, of whom 55, or 23.1 per cent., were approved and passed; 75 were rejected for physical disqualifications; and the remainder either withdrew or failed to pass.

Evidently the standards of the two Boards are about the same. The proportion of those rejected for physical defects is noteworthy. In a general way we may say that about one-fourth of the candidates before such boards are approved — and one-fourth fail on the preliminary examination as to general education. Putting aside those rejected for physical causes, and making the necessary corrections for a certain number who came before the boards more than once, we find that of 429 examined, 129, or 30.2 per cent. were successful.

Of those candidates who had a college degree, 34 per cent. succeeded, and of those who had no such degree, 28.9 succeeded. Of those candidates who had had one year's residence in hospital, 40 per cent. passed, while of those who had not been residents, only 21 per cent. were successful. The percentage of successful candidates from different schools varies greatly, ranging from 9 to 56 per cent., for those schools from which more than ten candidates presented themselves. I cannot go into details on this point, but may say that taking the Medical Schools of Harvard, Yale, the College of Physicians, and Bellevue Hospital of New York, the University of Pennsylvania, and the University of Virginia together, of 141 candidates, 65, or 46.1 per cent. succeeded, while for all the rest of the schools in a body, of 586 candidates, 64, or 22.3 per cent. succeeded.

The figures from Yale alone, are too small to draw accurate conclusions from, but in strict confidence I will tell you that of the five graduates of the Yale Medical School, who came before the Army and Navy Boards during the last ten years, three, or 66.6 per cent. have passed. The greatest percentage of successful candidates comes from those who were between 24 and 25 years of age when they graduated, being 31.7 per cent., as against 27.9 per cent. for those who were under 22, and 26.2 per cent. for those who were over 25 on graduation.

Admitting it to be a fact that different schools have different minimum standards for graduating Doctors of Medicine, to what extent are these differences necessary, or desirable? There is at present a very general demand that those schools which have the lower standards shall raise them to the ideal of the medical profession just stated. It seems as if the supply of physicians is now, in most parts of the country, in excess of the demand, the number of medical men being from two to three times as great amongst us, in proportion to the population, as it is in France or Germany, while the annual number of graduates also greatly exceeds the number of places to be filled.

Under these circumstances, there is necessarily a struggle for existence in which the men of inferior qualifications usually, though not always, fail. The schools, however, will not shape their course so much with reference to the real or supposed interests of the profession or of the public, as with reference to the demands of their immediate customers, the students, and many of these, as has been said, do not want any more education than is absolutely necessary to enable them to begin practice. The ability and inclination to pay for professional services differs greatly in different localities, and among different classes of people.

Attempts to enforce a minimum standard of qualifications, by prescribing a minimum time for the course, and a minimum for the number of lectures in certain specified branches, will not result in fixing an uniform minimum standard of results obtained, for this can only be assured and maintained by some system of inspection and testing of results which is independent of the schools or, at all events, of each individual school. When, as Professor Sumner says, "A and B put their heads together to see what C ought to be made to do for D," there is small prospect of result so long as C is free to do as he likes.

In the Russian myth, when the raven brought the water of life and the water of death to the gray wolf, the first thing that the wolf did was to test their powers on the raven himself to determine whether his task was properly done. The public do not have an opportunity of seeing the effect of such a test as this upon those who come to them from the schools professing to have obtained the knowledge of healing; if they had, the complaints of overcrowding in the profession would probably cease.

From the commercial point of view it seems plain that there are too many medical schools in this country, that the education which many of them are giving is a very poor one, and that the students who are attracted to these last by offers of a cheap and short course, waste their time and their money.

The only really efficient remedy for this state of affairs is a system of State examinations, with minimum standards. This also has its evils, since it must lead to cramming; but it is the best we can do at present. It is urged by some that this minimum standard should be uniform throughout the United States; but in that case, it would be unnecessarily low in some parts of the country. The precise nature of the requirements in different regions depend on the density of population, and on the ability of the great mass of the people to pay enough to induce highly educated physicians to settle amongst them. It would be better if it were otherwise, and if every one could have the benefit of the best professional skill; but matters are adjusted in this world largely by conflict of interests. Certainly no one who intends to practise medicine should be content with the least amount of knowledge which will enable him to pass the required examinations, whatever the standard of those examinations may be. Putting aside now this matter of a minimum standard, let us consider briefly an ideal of a medical education of a higher type.

In addition to the incipient family practitioner of ordinary qualifications — the beginners in the profession — there is need of, and employment for, highly skilled, thoroughly trained physicians and surgeons as family physicians, as consultants, as specialists, and as investigators and teachers.

There are two ways in which these needed men may be educated and developed. The first is by their commencing with the ordinary course of instruction for general practice in the manner just spoken of, and then going on, after graduation and commencing practice, to study and perfect themselves in details — according to individual tastes and opportunities; and this has been the course pursued by a large number of our most distinguished American consultants and specialists. The other is to lay a broad and sound foundation of preliminary education before giving any attention to clinical study or practice. This means an edu-

education at least equivalent to that required of candidates for the degree of Bachelor of Arts from our leading universities, including Latin, French, and German, and mathematics to include trigonometry, and the elements of analytics. It should also include one year's work in a physical laboratory, two years' work in chemistry, two years' work in biology, at least one year's work in practical anatomy, and one year's course in materia medica.

In other words, it requires that the youth of sixteen, having obtained a good high-school education, shall go on to spend at least five years in additional study before he commences to see anything of practice. He should then spend at least three years more in special medical and clinical studies, during one year of which he should, if possible, reside in a hospital. If then his purpose is to become a specialist, an original investigator and a teacher, it is desirable that he should spend two years more in clinics and laboratories devoted to his special subject—and at least half of this time should, at present, be spent abroad. These are the broad outlines of what I suppose most physicians of the present day, would consider a desirable scheme of medical education for an intelligent boy with a fair amount of liking for study, good health, and sufficient means to enable him to go through with it without making undue demands upon his parents or guardians.

You will observe that there are several qualifying clauses in that last sentence. The aphorism that it does not pay to give a five-thousand-dollar education to a five-dollar boy, must be constantly borne in mind in considering these questions. On the other hand, it is also to be noted that in the preparation of educational schemes, it is not necessary to provide for the demands of youths of extraordinary ability and industry—for men of genius. Beds suitable for giants are not required as part of the stock of an ordinary furniture store, especially if it require giants to make them. Some cases of disease will recover without treatment, though the cure may be hastened by proper management; some will die under any treatment; the result of some depends on the treatment. It is much the same in education. Some will acquire knowledge and power without special training; others will never acquire these things under any training; but the career of many depends, to a large extent, on the training which they receive. The recent announcement of a compulsory four years' course of medical studies by Harvard and the University of Pennsylvania, soon to be followed by a similar announcement from Columbia, looks toward the ideal just indicated.

The number of those who are obtaining a college education as a preparation for medical study has increased, and will still more increase as the competition among an excessive number of physicians becomes fiercer.

From information received from some of our leading medical schools for the present year, it appears that the proportion of students who have taken preliminary degrees before commencing the study of medicine varies from fourteen to forty-three per cent. in Eastern schools, from three to twelve per cent. in Western schools, and from fifteen to twenty per cent. in Southern schools.

Just here comes in a very difficult point. When shall general education cease and special training begin? The answer to this must depend largely on the individual, but it seems to me that the present tendency

is to begin to specialize too soon. This early specialization of study and work may lead to more prompt pecuniary success, but not, I think, to so much ultimate happiness and usefulness as the longer continuance of study on broader lines. "For it is in knowledge as it is in plants: if you mean to use the plant, it is no matter for the roots; but if you mean to remove it to grow, then it is more assured to rest upon roots than slips; so the delivery of knowledge as it is now used, is of fair bodies of trees without the roots—good for the carpenter but not for the planter. But if you will have science grow, it is less matter for the shaft of body of the tree, so you look well to the taking up of the roots."<sup>2</sup>

In discussions on medical education and the duties of medical schools, we are too apt to lose sight of the fact that the best that the student can do in them is to begin to learn. If he does not study much longer and harder after he graduates than he does before, he will not become a successful physician. Moreover, the great majority of men have different capacities for learning certain things at different ages. They lose receptive power as they grow older.

Permit me to use here a personal illustration, and pardon the apparent egotism of an old gentleman who refers to his youthful days. Thirty-three years ago I began the study of medicine, having obtained the degree of Bachelor of Arts after the usual classical course of those days. It so happens that the smattering of Latin and Greek which I obtained has been of great use to me, and I may, therefore, be a prejudiced witness, but my acquaintance with many physicians at home and abroad has led me to believe that the ordinary college course in languages, mathematics, and literature is a very good foundation for the study of medicine, and I do not sympathize with those who demand that all who are to enter on this study, shall substitute scientific studies for all the Greek and a part of the Latin of the usual course. This change is good for some but not for all. I had attended lectures in physics and chemistry but had done so laboratory work, and I could read easy French and German. Thus equipped I began to read anatomy, physiology and the principles of medicine. Nominally I had a preceptor; but I do not think I saw him six times during the year which followed, for I was teaching school in another State. Nevertheless, he told me what books to read, and I read them. The next thing was to attend the prescribed two courses of lectures in a medical college in Cincinnati. Each course lasted about five months, and was precisely the same. There was no laboratory course, and I began to attend clinical lectures the first day of the first course. One result of this was that I had to learn chemical manipulation, the practical use of the microscope, etc., at a later period when it was much more difficult. In fact I may say that I have been studying ever since to repair the deficiencies in my medical training and have never been able to catch up.

Probably a large number of physicians over fifty years of age have had much the same experience, and feel that there are certain things, such as the relations of trimethoxyethylene-ammonium hydroxide in the body, or the causation of muscular contraction by migration of labile material between the inotagmata—the bearings and beauty of which might as well be left to younger men. Not that these things are especially difficult to understand, but they form part of a

<sup>2</sup> Bacon.

new nomenclature which in most cases it is not worth the while of the older men to learn, because it is far more difficult for them to master it than it is for their sons. One of the most comfortable and satisfactory periods in a man's life is that when he first distinctly and clearly recognizes that in certain matters he is a hopeless old fogy, and that he is not expected to know anything about them.

### THE CHARACTER OF THE EVIDENCE AS TO THE INJURIOUSNESS OF ARSENIC AS A DOMESTIC POISON.<sup>1</sup>

BY J. J. PUTNAM, M.D.

It is well known that a large amount of evidence has been accumulating during the past half-century, indicating that the exposures of daily domestic life are sufficient to cause, under favorable conditions, almost every form and degree of arsenical poisoning. This evidence has found more or less recognition in the best text-books of every country, has attracted the attention of scientific men of judgment and eminence, — physicians, chemists and sanitarians — in every part of the world. Not only this, but every investigator of any weight who has approached the study of the action of arsenic from the purely physiological or pathological stand-points, and not from interest in the popular agitation of the subject, has accepted and utilized this clinical testimony so far as it has come in his way to do so.

One of the most recent of these is Alexander, of Breslau, the author of an excellent monograph on arsenical polyneuritis, one of the best recognized forms of arsenical poisoning.<sup>2</sup> Of fifty-eight cases of paralysis, which Alexander adopts, out of a much larger number, for special analysis, nine were of "domestic" origin, the rest being mainly acute cases of accidental or homicidal poisoning by large doses.

There are several ways in which this subject may be regarded:

(1) We may discard the affirmative evidence altogether, and conclude that the long list of eminent men who have admitted it, are wholly mistaken. This position is rarely maintained, but it has been taken by Prof. Alfred Chandler, of Columbia College, the single expert who has testified adversely when attempts have been made to obtain protective legislation in this State.

(2) We may consider that poisoning does occur, but so rarely that it is not worth any one's while to regard it as a practical danger.

(3) We may admit that poisoning occurs, and, in view of the extreme commonness of the exposure, may search conscientiously to see whether it does not occur more commonly than has been supposed, but pass often unobserved, partly because this diagnosis is not in the physician's mind, and partly because the symptoms are often obscure and attributable to other causes.

It is this view that I desire to maintain; and it may be noted in passing that if it should turn out to be the correct view, there would be no occasion for surprise,

since the history of medicine is full of examples of the long overlooking of the most obvious clinical truths. This very matter of multiple neuritis is an instance in point. Although characteristic cases had been occasionally described before, it is only twenty years since the profession was really taught to recognize them, and yet it turns out that they are of the most common occurrence.

Some of the reasons that have been urged against the occurrence of arsenical poisoning from "domestic" exposure call for careful consideration. Little or no weight, on the other hand, should be attached to the sentiment of simple disbelief with which the suggestion of this diagnosis is often met. When, for example, a patient presents himself with the symptoms of multiple neuritis, for which no special cause can be found, and at the same time is found to be excreting arsenic, it is not in any physician's power to deny that his disease *may be* of arsenical origin. He may assert that this diagnosis is not by any means proved, and may prefer to hold his judgment in abeyance, but it is a simple obstruction to scientific progress, and a misuse of diagnostic methods, to bluntly deny the possibility that this diagnosis may be correct.

One of the strongest arguments that is brought forward to show the improbability of arsenic poisoning is, that physicians often give their patients far larger quantities of arsenic than could be derived from domestic exposure. I shall endeavor to demonstrate that poisoning from therapeutic doses is more common than has been supposed; but it should not be forgotten that, so far as the validity of the argument is concerned, it might be used with equal force to prove that poisoning could not occur from doses even far larger than those used in medicine, since it is well known that the Styrian peasants learn by habituation to take with impunity quantities which would ordinarily be almost certainly fatal.

The whole line of argument which I offer in regard to the domestic cases is:

I. — That the actual absorption of arsenic in consequence of the exposures of daily life is extremely common, as is demonstrated by urine analyses.

II. — That arsenic accumulates in the tissues, so that the elimination of a certain quantity implies the presence of a far larger quantity in the body.

III. — That the clinical cases may be divided, for convenience, into three classes: (1) those where the arsenic causes acute irritation of the mucous membranes without necessarily being present in the tissues in any large quantity; (2) those where the accumulated arsenic exerts all at once a poisonous action; (3) those where simple disorders of the general or local nutrition are gradually set up through the action of minute and repeated doses.

IV. — That poisoning is liable to occur under all these conditions during the therapeutic use of arsenic.

V. — That the character of the preparation and the mode of absorption materially affect the danger of poisoning.

I. — The proof of the frequent absorption of arsenic is given by the urine analyses, now amounting to many hundred, which have been made by chemists in various countries, but especially by those of Harvard University. I shall refer only to the investigations of Dr. C. P. Worcester, who has carefully analyzed more than one hundred and fifty specimens by the most approved methods, and has found arsenic in more than thirty per

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Massachusetts Medical Society, Suffolk District, April 22, 1891.

<sup>2</sup> Inaugural Dissertation on Arsenical Paralysis, Breslau, 1889.

cent., in quantities varying from five hundredths of a milligramme to nearly one-tenth milligramme, per litre.<sup>3</sup>

This investigation was begun about two years ago, at my request, and the specimens of urine were, to a considerable extent, furnished by patients in attendance at the Out-Patient Department of the Massachusetts General Hospital. Some of them presented symptoms which might possibly have been due to arsenical poisoning, though they were not characteristic of it, but others were selected as not presenting any such symptoms. The rest of the specimens were from private patients of my brother and myself.

These results are extremely important, and the conclusions to which they point should not be misunderstood. They indicate first, a very wide-spread exposure on the part of the community at large, for the persons who are the subjects of the investigation were selected largely at random. The argument that arsenic cannot be absorbed from domestic sources is thus absolutely disproved. With regard to many of these patients it could be asserted positively that they had taken no arsenic in the form of medicine; and in a number of the cases it was traced to one or more definite exposures and gradually disappeared when these were removed.

They show, next, that the simple finding of arsenic in the urine does not prove that a given patient's symptoms are of arsenical origin. Finally, such analyses are certain to prove a valuable aid in studying the obscure cases of arsenical poisoning, at least to the extent of eliminating with considerable probability the non-arsenical cases, and they are of importance with relation to arsenical therapeutics.

II. — What conclusions can we draw from these results as to the accumulation of arsenic in the tissues?

It was formerly believed that arsenic was eliminated rapidly; that it did not, like lead, form albuminoid compounds within the body. These opinions are now found to be incorrect. Arsenic does form albuminoid compounds,<sup>4</sup> and it is eliminated very slowly, having been found in the liver and bones six months after the cessation of medicinal treatment, which led to the patient's death (Gibb), and having been found in the urine six, and even nine, months after apparent removal from exposure in "domestic" cases, where its eventual disappearance substantiated the belief that the true source of the contamination had been found (Harrington, Coney and others). Prof. E. S. Wood has found arsenic several months after cessation of a short course of treatment and after homicidal poisoning. (This investigation is still unfinished, but I am at liberty to state its general outcome.) The daily elimination, therefore, represents only a small fraction, in many cases at least, of the amount present in the tissues; and as the exposure in the "domestic" cases is often of months' and even years' duration, it is evident that the accumulation might eventually be considerable.

III. — With regard to the types of arsenical poisoning I will not occupy your time by speaking of them at length. The important thing to remember is that we should not deceive ourselves as to what we are to expect. It is probable that in by far the greater number of cases of domestic exposure no ill result follow, but one who takes the trouble to investigate the literature of "domestic poisoning" will find

that there is a certain number of typical cases. As I am, in this paper, only seeking to establish the possibility of arsenical poisoning, I will only refer to the cases of neuritis, and to save space, only to my own experience. I have seen at least three typical cases of neuritis with impaired electrical reactions and the usual sensory and motor symptoms, where every other cause could be excluded as rigidly as is ever possible. I will not give the details here because I propose at another time to make a full collection of the cases observed by others as well as myself. Besides these typical cases, I have seen a number of cases of chronic neuritis where this diagnosis was the most probable one.

In this connection I desire to call attention to one very important consideration. It is often asked, Why is it that people so long exposed to arsenical poisoning do not sooner show the effects of it; and why are not more persons poisoned? It would be a practically sufficient answer to these questions, to assume that the persons not affected were protected by habituation and natural tolerance; and to point out that of persons exposed by their occupations to lead poisoning, such as painters, only a very small percentage are seriously affected. It is, however, my belief that, in spite of the immense protection given by natural or acquired tolerance, there are various occasional effects of lead and arsenic poisoning which are, as a rule, wholly overlooked. The only pieces of evidence of this to which I wish to call attention here are those pointing to the existence of a pre-paralytic stage of arsenical and saturnine neuritis.

It was long ago pointed out by Erb that in cases of lead poisoning it was not uncommon to find that certain muscles showed an impairment in their electrical reactions, although they were not paralyzed. Again, Gombault, in his oft-quoted researches into the pathology of neuritis due to lead, found signs of well-marked change in the peripheral nerves in guinea-pigs who had been given a small quantity of lead for some time, although they had shown during life no impairment of voluntary motion. As to arsenic, it is well recognized to be a fact, that when paralysis follows a single large dose, or a number of smaller doses, its appearance is often delayed for weeks and even months.

Furthermore, the observations to which I have already referred, on the elimination of arsenic, make it clear that recovery may begin and progress in cases of paralysis while the tissues still contain arsenic. Such facts as these make it practically certain that the occurrence of outspoken paralysis, either of sensation or motion, is not a necessary accompaniment of a greater or less degree of neuritis. It is inconceivable that a single dose of arsenic sufficient to cause violent poisoning and eventually serious paralysis should not begin to affect the nutrition of the nerves during the days, weeks or months before the paralysis appears.

The fact that paralysis is a relatively uncommon symptom of arsenical poisoning strengthens the supposition that paralysis is only a final and gross symptom of the neuritis which must have been going on before. Not only this, but in my opinion, we need not lean upon assumptions alone for indications that this pre-paralytic neuritis is comparatively frequent. During the short period that covers the modern history of neuritis, the indications that peripheral nerve changes are extremely common have been multiplying in a way that was wholly unexpected. Let every one examine

<sup>3</sup> The estimations were made by comparison of the nitrons with a table, which has been proposed by Professor Sanger, now of Andover, and Prof. H. E. HILL, of Cambridge.  
<sup>4</sup> *Deutscher Natur. Congress, Copenhagen, 1882.*

his cases of suspected arsenical poisoning by careful electrical tests and for the slightest motor and sensory disorders, and I think he will occasionally find that he has not been able to diagnose some of the lesser degrees of neuritis, simply because he has overlooked a characteristic sign and has waited for indications which were really not to be expected in the early stage of the disease.<sup>5</sup> During the past month I have seen a case of well-marked alcoholic paralysis where the symptoms had been present in an outspoken form only for a few weeks; but on questioning the patient carefully, it appeared he had suffered for a number of months with a slighter form of the same trouble.

Space forbids my speaking at length of the other groups of symptoms indicated above. I will only say that the admitted history of arsenical poisoning proves that this may be manifested only by anæmia, local neuralgias (neuritis, herpes-zoster), by the failure of special functions (sexual impotence, loss of voice, etc.). While it may be impossible to make a positive diagnosis of arsenical poisoning from the presence of such symptoms as these, it would be idle to deny that this might be, in a given case, the cause. If the severe cases occasionally occur as a consequence of such a long exposure to continued doses, these more insidious cases would be, in all probability, far more common, and this especially in the case of feeble persons and infants.

IV. — It is often assumed that, because arsenic carefully used as a medicine may eventually be tolerated in large doses, therefore there is no danger in its therapeutic use. This is founded on grave misapprehension of facts.

The first stages of poisoning (œdema of the face, diarrhœa, vomiting, prostration, albuminuria, etc.) are very common; and the experiments of Vaudrey have shown that these signs, which by a strange euphemism are sometimes called the signs of the "physiological action" of arsenic, are really the first indications of poisoning, which a rash persistence might render dangerous. Not only is this the case, but, as is proved by a number of cases, some of which I collected three years ago,<sup>6</sup> unusual susceptibility may render ordinary doses highly dangerous, and protracted treatment may eventually lead to the outbreak of acute poisoning.

V. — The form in which arsenic is actually absorbed in "domestic" cases is not yet positively settled. If the gaseous theory is still unproved, yet it is not fully disproved. There are certainly a number of clinical facts which obstinately resist the acceptance of the "dust" doctrine as the only admissible one. In the mean time it is positively known that the different compounds of arsenic differ greatly in their poisonousness, and it is known further that the mode of its introduction into the system is also important. The stomach, in a measure, protects the patient from danger of certain kinds, and it may be that this is not true, to the same extent, of the lungs. In the experiments of Alexander, above alluded to, it was found that arsenic injected under the skin was three or four times more poisonous than the same amount injected into the peritoneal cavity. It should also be borne in mind, if we wish to deal fairly with the "domestic" issue, that the exposures are often multiple. I know of several cases where a dozen or

fifteen papers in one house all contained "dangerous" quantities of arsenic. Recently noted sources are distemper paints used for frescoing, and the dust which accumulates in carpets and carpet papers. When it is remembered how easily this dust is raised by walking, and that a twentieth of a grain of arsenious acid is a full dose, and two grains may be a poisonous dose; and when it is further remembered that when a room is dusted or swept, or the walls cleaned, only a portion of the material set free is entirely removed, the rest settling on the furniture and floor, it is not difficult to understand that dangerous quantities may occasionally be inspired.

One more fact, which is thoroughly established by the history of typical arsenical poisoning, should be borne in mind. This is, that the persistent use of small or moderate doses is not always followed by the same results. The most common effect is probably habituation and tolerance, but cases are not infrequently seen where the sensitiveness to the drug is greatly increased. That fact has been pointed out by Isnard, among others,<sup>7</sup> one of the most enthusiastic advocates of arsenical medication. It is, indeed, rather commonly believed that when symptoms of poisoning have actually occurred, this increased susceptibility regularly shows itself. This cannot, I think, be maintained. I have certainly seen one case of very severe multiple neuritis, with pain and atrophy, where no cause except arsenical poisoning could be found; yet the patient subsequently took arsenic combined with iodide of potash, without a recurrence of his former symptoms.

To sum up, it may be said that competent persons have seen typical cases of paralysis and other symptom complexes for which arsenic poisoning would be an adequate cause, and where arsenic has been found in the urine, and the symptoms have followed the course that they would be expected to follow if due to arsenical poisoning.

The only ground on which to refuse to admit the possibility of arsenical poisoning, under these circumstances, would be strong presumptive arguments against that view. I have tried to show that such presumptive arguments do not exist, but that, on the contrary, the urine analyses abundantly indicate the presence in the tissues of quantities of arsenic such as have actually caused symptoms of poisoning when given as a medicine; and that the use of arsenic as a medicine, although rarely harmful, needs careful watching. In the cases of domestic exposure, arsenic is being absorbed in minute but accumulating amounts without its effects being watched. The reason that no more persons are severely poisoned is the same that prevents a great majority of painters from being affected with lead poisoning; but in both cases general and local disorders of nutrition are liable to occur and to be wholly overlooked unless carefully sought for. Further analogies between the action of lead and that of arsenic exist, and will be studied more carefully in another paper. I have also indicated certain reasons for believing in a pre-paralytic stage of arsenical neuritis; and it might be added that a post-paralytic stage also exists, inasmuch as the recovery from arsenical neuritis begins and progresses while the patient is still eliminating arsenic from the urine. It is even conceivable that during the recovery from arsenical neuritis the administration of arsenic in small doses might

<sup>5</sup> See case in *Boston Medical and Surgical Journal*, March 7, 1889.

<sup>6</sup> *Boston Medical and Surgical Journal*, July 5, 1888.

<sup>7</sup> *L'Arsenic*, Paris, 1865.

be beneficial, for it is probable (Ziegler and Abolonski. Alexander) that the therapeutic and the toxic effects of arsenic differ only in degree, and the increase of cell activity which has been shown to occur, for certain organs at least, seems to go on side by side with cell destruction.

#### A CASE OF SYPHILITIC ENDOCARDITIS WITH REMARKS.<sup>1</sup>

BY EDWARD M. GREENE, M.D.,  
Pathologist to Carney Hospital and Boston Dispensary.

THE importance of syphilis as an etiological factor in cardiac disease, has attracted very little attention until lately. A brief report of a case in which endocarditis manifested itself during the secondary stage of syphilis, may therefore be of interest.

The patient, M. F., was a young, unmarried woman, aged twenty-three, a photograph retoucher by occupation. The family history was good. At the age of eighteen years she had typhoid fever, and one year ago *la grippe*. Otherwise her health had always been good, and she had never suffered from rheumatism. Her habits had not been virtuous. Two years ago she gave birth to a healthy child at full term. Has never had a miscarriage.

I saw her first in August, 1890. She was well developed and nourished, and not anæmic. She had been confined to bed for several days with pain in the pelvic region and profuse flowing. Her menstruation previously had been normal. She was somewhat feverish, and there was considerable tenderness just above the pubes. These symptoms subsided during the next week, but she then began to complain of constant headache and considerable pain in the back and limbs. She was moderately feverish, but had no tenderness or swelling of the joints. Careful examination showed absence of murmurs or other evidence of cardiac disease.

Two days later a profuse eruption of pustules of the size of a split pea and smaller, appeared on the forehead, and soon after and in smaller numbers pustules appeared in the scalp, over the back, on the arms, and in the palms of both hands. There was a mild pharyngitis. Enlarged glands were found in the groins and about the neck. She complained of soreness under the sternum. A faint but distinct systolic murmur was now heard for the first time at the right of the sternum, over the aortic valve. The heart was otherwise normal and there was no venous murmur in the neck. She was given one-sixth of a grain of protiodide of mercury three times a day, and mercurial ointment to apply to the face. In less than two weeks the eruption had disappeared from the face but persisted in a milder form in the scalp and over other parts of the body. A number of large, reddish papules were also seen on the back and chest. The murmur over the aortic valve was decidedly louder. Her general condition was very much improved and she did not consult me again until January, 1891, nearly three months later. The pustular eruption had disappeared in October, and she had not taken her medicine for about two months. She was now complaining of headache, sore throat, loss of hair, general weakness and poor appetite. She was somewhat anæmic. There was a macular patch on the right

cheek, opposite the molar teeth, and a small ulcer in the corner of the mouth. A considerable number of dark reddish papules were seen scattered over the trunk and extremities, and here and there were a few pustules. There was considerable œdema about the ankles, so that at times she could not put on her shoes. The area of cardiac dulness was not increased. A distinct, rather loud, systolic murmur was heard, the maximum intensity of which was in the second intercostal space at the right border of the sternum. It was also heard over the carotid arteries. There was no venous murmur in the neck. The second pulmonic sound was decidedly louder than the aortic. The pulse was regular but rather weak, and 90 in a minute. She now began to take four doses daily of one-sixth of a grain of the protiodide of mercury. During the next four weeks the eruption almost disappeared, and the general condition improved. The cardiac condition, however, remained unchanged.

We have then a case in which cardiac symptoms were developed in a severe case of syphilis during the secondary stage. The reasons for thinking that the cardiac murmur was of organic rather than of anæmic or functional origin, were: It was constant and limited to the region of the aortic valve and carotid arteries; there was no murmur in the region of the pulmonary valve or viens of the neck, such as is commonly heard in anæmia; the second pulmonic sound was accentuated; lastly, the appearance of œdema of the ankles.

We conclude therefore, that there was acute endocarditis of syphilitic origin. The fact that the murmur did not disappear under antisyphilitic treatment, does not prove that the lesion was not syphilitic any more than the failure of salicylic acid to remove the evidence of endocarditis occurring in an attack of rheumatism, proves that the lesion in the latter case is not rheumatic. The infrequency with which endocarditis is discovered in syphilitic cases may, perhaps, be explained in part by the rarity with which examinations of the heart are made in such cases.

Dr. Alfred Buchwald,<sup>2</sup> of Breslau, presents a statement of his large experience in cases of cardiac syphilis. He is convinced by a large number of cases which he has treated during the last six years, and a part of which he has kept under observation, that syphilitic disease of the heart, especially myocarditis, is a far more frequent disease than is supposed; that the peculiarities of the disease are sufficient to permit of a diagnosis being made; that through antisyphilitic treatment, not only improvement but even cure can be brought about. He can count up more than twenty cases of his own of which the syphilitic origin is certain. They are mostly of men of the better class. Among laborers a diagnosis is much more difficult because excessive exertion and abuse of alcohol cannot be excluded as etiological factors. The patients were all in the prime of life, from twenty to forty years of age. The length of time which intervened between the syphilitic infection and the development of the heart lesion was, in the majority of cases, from six to ten years. Some of them still had affections of the skin and glands; in some there was emaciation, anæmia and cachexia. In three cases, without the intervention of rheumatism, there was developed evident valvular disease — aortic and mitral insufficiency. In all the cases every other etiological element — as abuse of alcohol and tobacco, and rheumatism — was

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, April 22, 1891.

<sup>2</sup> Deutsche. Med. Wochenschrift, December 28, 1889.

certainly excluded. Not only was syphilis unmistakably indicated by the symptoms, but its existence was demonstrated by cure being brought about by anti-syphilitic treatment consisting of mercury or iodide of potash.

The symptoms in the majority of cases were: headache, dizziness, flashes of light, loss of strength, palpitation, dyspnoea, feverishness, sore-throat. In some cases there were symptoms of angina pectoris, and neuralgic pains like those of aneurism. In all cases there was irregularity of the heart, more or less hypertrophy, and what is especially noteworthy, alterations in the peripheral vessels such as are commonly ascribed only to old age. The arteries were hard and tortuous, more especially the temporal arteries, and, to a less extent, the radials. The course of the disease was also characteristic. The cases in which the heart insufficiency could no longer be influenced favorably quickly ran down hill, developing marked anæmia and consecutive kidney disease and sometimes repeated pulmonary infarction, with hæmoptysis. The majority of cases showed a great and rapid improvement under purely anti-syphilitic treatment. One case that developed aortic insufficiency while under observation was so much improved that no trace of this lesion was recognizable. Another, whose heart lesion was cured, developed sudden aphasia and cerebral disease, but recovered from this also under large doses of iodide of potash. In other cases the peripheral arteries recovered from their hard and tortuous condition. The author has no doubt that a great number of syphilitic persons will, sooner or later, develop syphilitic myocarditis, with or without vascular disease. The importance of early diagnosis and of anti-syphilitic treatment is obvious.

### CASES OF RENAL COLIC.<sup>1</sup>

BY GARDNER W. ALLEN, M.D.,

*Surgeon in the Genito-Urinary Department, Boston Dispensary.*

The following cases were of interest to me on account of the suddenness, severity and short duration of the symptoms. I have used the term renal colic advisedly, not caring to commit myself to a diagnosis between nephralgia and the passage of renal calculus.

CASE I. The patient, a man seventy-two years old, got up on the morning of July 4, 1889, feeling as well as usual, and he was a strong, healthy man for his age. An hour or two after breakfast he was suddenly seized with a very violent pain in the back and right side. I saw him soon afterwards, and found him in great agony and distress from the intensity of the pain, which was situated in the region of the right kidney, and from this point extended around into the right groin. The right testicle was drawn up. Morphine was given subcutaneously in repeated doses until the pain was relieved, and I then left him in a state of comparative comfort. I called on him late in the afternoon, and was surprised to find him sitting up down stairs, apparently as well as ever. He has remained well up to this time, having had no symptoms except transient, darting pains in the right groin, which are rather frequent, but which he has been subject to for many years; he attributes them to a blow he received in the right groin thirty years

ago. He is certain that he never passed a stone by the urethra.

CASE II. A physician, about thirty-five years old, was in perfect health on the evening of June 5, 1890. He had never before had any renal or urinary symptoms. About 11 o'clock he urinated, preparatory to going to bed. A few minutes later he began to have a severe bearing-down pain over the bladder, then an intense, lancinating pain in the region of the right kidney, with retraction of the right testicle. Micturition, at intervals of five minutes or less, was only possible in the knee-elbow position; a few drops only passed at a time, after waiting and straining. Chills and nausea. I saw him the next morning, and found that he had taken a good deal of morphia, and was comparatively free from actual pain. The urinary symptoms, however, had continued unabated all night, and had wholly prevented sleep. During my stay there was constant tenesmus, and he was forced to get out of bed every two or three minutes, when, after straining on his hands and knees for some seconds, he would pass a very few drops of urine. There was not enough in all to furnish a specimen for examination, but it looked perfectly normal; it contained no blood then or afterwards. There was tenderness on pressure over the right kidney. I advised hot sitz-baths, counter-irritation, diuretics, and morphia and belladonna suppositories. In the evening he was much more comfortable. He had had no more pain; the tenderness over the kidney had disappeared; and the urinary symptoms had gradually subsided. There had been nausea and vomiting in the afternoon. He had used only one suppository, but seemed dull, confused and drowsy. The next day he was very weak, and had slight, darting pains in the perineum which lasted a few days; then all symptoms disappeared. He convalesced rapidly, passed nothing per urethram to account for the attack, although the urine was carefully examined for two weeks, and has not had the slightest renal nor urinary symptom up to this time.

CASE III. The patient, a man forty-five years old, was seen August 5, 1890; and I take from my records the following notes:

Has had similar attacks to the following before, the most severe two years ago, which was promptly relieved by morphia. Five days ago he began to have pain in the right loin, but it has not been severe until a few hours ago. It is now (11 p. m.) very severe and constant. The pain begins in the right back and side, below the kidney, and passes down in a line parallel with Poupart's ligament into the scrotum, the right testicle being retracted. There is no nausea nor any other symptom except a slightly increased frequency of micturition with a sense of irritation at the neck of the bladder. The treatment was counter-irritation and morphia of which one and a half grains were given in divided doses before relief from pain, and sleep were obtained. He awoke the next morning free from pain and feeling nearly as well as ever. He has since remained entirely free from symptoms of this nature, and has never passed a stone by the urethra.

I have not made extensive researches into the literature of this subject, but apparently most authorities assume the presence of renal calculus in cases of this sort. When the stone is not found, it may have been passed through the urethra without attracting the patient's attention, or have become dissolved in the

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, April 22, 1891.

bladder. It seems to be a question, however, whether these symptoms may not be purely neuralgic in certain rare cases.

I will conclude by quoting the following paragraph from the article on "Diseases of the Kidneys" by Dr. R. T. Edes in Pepper's "System of Medicine," which seems to me an excellent summary of the subject:

"Renal colic is the appellation of a group of symptoms caused, in by far the greater proportion of cases, by the passage of a renal calculus through the ureter, or sometimes merely its engagement in the upper extremity and impaction or subsequent falling back. Other foreign bodies large enough to cause distention and obstruction, such as clots of fibrin or portions of hydatid cysts, may give rise to the same phenomena. Most physicians, however, have seen cases where the same set of symptoms have not been followed either by the discharge of the stone per urethram or by evidence of its continued sojourn anywhere in the urinary organs. They may occur in persons of a neuralgic tendency in connection with the uric or oxalic diathesis. The conclusiveness of such cases, as proving the possibility of a purely neuralgic or spasmodic attack, must, of course, depend upon the carefulness and intelligence of the patient and the opportunities of the physician for observation extending over years. As it is admitted, however, that these symptoms may occur without the demonstrated presence of a calculus, it would be perhaps better nomenclature to apply the term renal colic to painful and spasmodic affections of the kidney and ureter, however caused, and to describe the passage of a calculus or other obstruction under its own name."

## RECENT PROGRESS IN THE DISEASES OF CHILDREN.

BY T. M. ROTCH, M.D.

### BRONCHIECTASIS IN YOUNG CHILDREN.<sup>1</sup>

THE author reports six cases, with autopsy, of this somewhat rare disease of childhood. It is, of course, always secondary to some antecedent lung trouble, bronchitis, pneumonia or pleurisy. A typical clinical history is something as follows: A child, perhaps ill-nourished or rickety, contracts measles or whooping-cough, or, as is so often the case, one soon after the other. The bronchial catarrh attending those diseases rapidly extends down in a weakened child, and sets up an acute bronchitis or broncho-pneumonia. The acute specific fever, *per se*, further weakens the child, and if not fatal, the pulmonary mischief tends to become chronic. In fact, catarrhal pneumonia, complicating measles or whooping-cough, is prone to be subacute throughout. From all these causes combined, the elasticity of the bronchial tubes is impaired, and they become readily dilatable, and thus the train is laid for securing the rapid development of bronchiectasis. While for convenience in description we classify separately bronchitis, broncho-pneumonia, pleurisy, etc., in reality these conditions are usually intermixed, more so in children than in adults, and most of all in young children. In them we often find bronchitis, patches of collapse, perhaps some lymph on the pleura, and at the same time diffuse broncho-pneumonia. Bronchiectasis, as a rule, results from a combination of these

various causes rather than from any one alone. It is not certain whether the pathological condition is due to passive dilatation of the bronchi or to the formation of fibrous tissue outside of them, but the author believes that both conditions contribute in nearly every instance. Chronic bronchitis weakens the elasticity of the bronchi, and catarrhal pneumonia is always accompanied by bronchial dilatation, which is increased by coughing. This dilatation, by permitting retention of secretion, perpetuates the inflammation, which gradually extends to the interalveolar connective tissue, and sets up fibrosis there. This fibrous tissue contracts, and thus drags apart still farther the weakened walls of the bronchi. The symptoms in the cases reported were variable and quite uncertain. In several there was a paroxysmal cough, but in no instance was there any factor of breath. The temperature, unless influenced by acute inflammatory attacks, was normal, and in late stages was subnormal. The physical signs were often those of cavities, and would seem to show rapid destruction of lung tissue, but at the same time the child would gain in strength and flesh, and had no elevation of temperature. In some cases there was a marked variability in the physical signs from time to time. The prognosis, if the disease is extensive, is very bad, but must be founded on the results of repeated physical examination rather than the delusive hopes founded on improvement in the general condition. Of treatment, unfortunately, but little can be said, except to emphasize the importance of prophylaxis. The condition is a practically incurable form of organic lung-disease.

### SO-CALLED CATARRHAL PNEUMONIA OF MEASLES AND WHOOPING-COUGH.<sup>2</sup>

The author's investigations were made upon nine cases, which he has arranged into two groups, and showed the following data:

(1) The individual foci of disease in the lungs were not larger than a pea. The alveoli contained round cells or epithelial or both, mingled with a small quantity of blood and fibrin. These foci were caused by the obstruction of a small bronchus with subsequent atelectasis and inflammation, or by the reception of infectious material within the alveoli. Those foci which formed in the vicinity of the pleura, always extended as far as the pleura.

(2) The foci in this group were larger than those in the first, the connective tissue around the bronchi was increased and rich in nuclei, and the connective tissue proliferation extended to the nearest alveoli and infundibula.

Peculiar to these foci was the occurrence of giant cells, without tubercle bacilli, and a typical epithelial proliferation. The numerous giant cells, which always lie in the alveolar spaces, are caused either by the cohesion of epithelial cells which have been cast off, or by flat epithelia which come from the alveoli. They may be enormously large, filling an entire alveolar space, and composed not alone of round epithelial cells, but also of blood-corpuscles and detritus, or they may be the result proliferation of cubical epithelium, as Friedländer has supposed. This author has described a typical epithelial proliferation, which proceeds from cylindrical bronchial epithelium at certain points where proliferating connective tissue adjoins the smaller bronchi. Kromayer has not recognized

<sup>1</sup> *Conn. Pract. Lectures*, Feb., 1891. *Archiv. Pediat.*, May, 1891.

<sup>2</sup> Kromayer: *Jahrb. f. Kinderh.*, xxvii, 1, 2. *Archives of Pediatrics*, May, 1891.

the association of these proliferations with cylindrical epithelium, but he believes that the explanation which has been given is the correct one, and that it is possible that these atypical epithelial proliferations may signify a regeneration of the changed alveoli. The parenchymatous processes around the bronchus in the foci of the second group are independent of the interstitial inflammation of the connective tissue accompanying the bronchus and between the peripheral foci, if they are not of very great extent, and the pleura is always found containing interstitial tissue. The first and oldest interstitial processes commonly begin at the point of division of a bronchus. Interstitial peribronchial inflammation is not only the cause of the pneumonic dilatation of the alveolar spaces, but also the cause of the continued presence of the exudation, since through the agency of the proliferating connective tissue the lymph-vessels are partly obliterated, and partly limited in their capacity for absorption. In a disease of this character which runs a chronic course such an explanation as has been given explains the development from pneumonia in children, of bronchiectasis, cirrhosis and phthisis, better than the supposition that there is a merely superficial inflammation.

#### TUBERCULOSIS IN EARLY CHILDHOOD.<sup>3</sup>

The proposition is advanced as tenable that a real hereditary tuberculosis can occur either from tuberculosis of the ovum, of the fructifying semen, or *in utero* from tuberculosis of the mother. The author is inclined to accept the view of Wolff, based upon experimental investigations, that a transmission of tuberculosis to the fœtus during conception is improbable. On the other hand, tuberculosis of the fœtus might arise from conditions in the uterus, in the placenta, or in the general condition of the mother. No account can be taken of an hereditary disposition, because there is always the probability that the delicate children of phthisical parents may have acquired their tuberculosis by intimate association with them after birth. At the Basel Hospital for Children, between the years 1870 and 1888, there were three hundred and three cases of tuberculosis in children under four years of age. Of this number, one hundred and forty-one died and were submitted to autopsy; the remaining one hundred and sixty-two were cases of bony tuberculosis, and were the subjects of operations. Of the entire three hundred and three cases, thirty-four per cent. came from tuberculous families. In forty-four per cent. of this latter number there was a history of pulmonary phthisis; and in thirty-four per cent. there was tuberculosis of the bones. In forty-three per cent. of the entire number of children there was tuberculosis of the bones; in thirty-one per cent. there was milary tuberculosis; in twenty-one per cent., tuberculosis of the lungs, and in the remaining four per cent., tuberculosis in different organs. The first year of life included eighteen per cent. of all cases, the second forty-two per cent., the third twenty-one per cent., and the fourth nineteen per cent. In sixty-five per cent. of those who died from pulmonary phthisis, there were gastro-enteric phenomena during life, and in thirty-five per cent. there was swelling or caseation of the mesenteric glands. In such cases it is believed that cows' milk plays a very important rôle as a source of infection. The statistics concerning tubercular basilar meningitis

give the following data: In one-third of all the cases there was probability of infection within the family; in two-thirds of the cases there was caseation of the bronchial glands. In seventeen per cent. there were operations on tuberculous bones, and in eight and three-tenths per cent. of those who were not operated upon, the bone-tuberculosis resulted in basilar meningitis. In sixteen per cent. of the cases there was milary tuberculosis, three-fourths of them showing cheesy bronchial glands. In less than fifty per cent. of the cases the source of the general infection was in a cavity in the lungs. Tuberculous bone-diseases are especially prevalent in the first and second years of life. In one-third of all the cases the source of infection is within the family. Traumatism preceded tuberculous bone-disease in twenty per cent. of cases, especially in connection with spondylitis and coxitis. In all but two of the cases of bone-disease which were examined post-mortem there was tuberculosis of the lungs, pleura, or other organs. There is an undoubted relation between operations for tuberculous bone disease and general infection, especially if the operation be resection of the hip joint. In twenty-one per cent. of all tuberculous cases, rachitis was present. The author's investigation did not demonstrate the influence of heredity in the particular sense of the term, but in thirty-four per cent. of the cases there was a chance for infection within the family, and the opinion was reached that tuberculosis might arise by direct infection.

#### THE BACTERIAL RELATIONS OF TUBERCULOSIS.<sup>4</sup>

The author's bacteriological investigations have a particular interest to pediatricists, because they were made upon the pathological material of the Children's Hospital at Pesth, and also demonstrated certain peculiarities in the clinical course of tuberculosis in children. The author found that tuberculosis itself seldom led to a fatal result, but that in most cases there were with the bacilli other pathogenic micro-organisms in the accumulations of the tuberculous disease or in the organs in general. By the increase of the micro-organisms in the tuberculous tissue, the latent pulmonary phthisis may be awakened, and then will rapidly follow the softening and destruction of the tuberculous products and the extension of the disease to surrounding tissues. Or these pathogenic micro-organisms before mentioned may remain limited to the tuberculous tissue, and form there with the tubercle bacilli particular products, such as the suppurating material in tubercular meningitis. In most cases the primary tuberculous focus is simply the avenue of entrance through which most of the group of micro-organisms belonging to the pyogenic cocci force their way into the body, proliferating from this starting-point, and occasionally produce septic or hemorrhagic processes, fatty degeneration of parenchymatous organs, and then a quickly fatal result. Clinically, the last-mentioned process would be considered an acute exacerbation of a chronic phthisis, or one which had become latent for a second time, and not infrequently it is associated with scarlet fever, measles, or some other acute infectious disease. The author's investigations have been very extensive and cannot receive justice in a brief abstract. They are of the greatest importance with reference to the clinical course of tuberculosis, and will give rise to further investigations in this direction.

## DISEASES OF THE HEART IN CHILDREN.\*

The various periods through which a case of heart disease may pass may be discussed under three heads: (1) Acute inflammation; (2) The establishment and maintenance of compensation; (3) The rupture of compensation and failure of the heart.

(1) Acute inflammation. — Causes are numerous, but rheumatism is far the most common; but the fact that it is so often "latent" and very difficult of detection, should never be forgotten. Endocarditis is the disease most often present, but pericarditis is found in many cases, and is frequently rheumatic in character, and the sooner we discover this fact the better for all concerned. Four tests may be employed to determine whether pericarditis be rheumatic or not: (1) The presence of an endocardial murmur; (2) The effect of anti-rheumatic treatment; (3) Tenderness of the joints; (4) The family history.

Several important differences in physical signs must be borne in mind in the examination of these cases in children. The heart lies higher, the apex-beat being usually in the fourth space, and more to the left than in the adult. The impulse is often widely visible and palpable. The sounds have a puerile character, being divided, both periods of silence being marked, and frequently deliberate or slow in development. The prominence of the præcordia is especially striking, friction fremitus is distinct, and friction sounds are relatively loud. The area in the back over which systolic murmurs are frequently conducted is often extensive. The author believes it unwise to give a too favorable immediate prognosis. It is no doubt true that acute rheumatic and chronic inflammation of the heart rarely proves directly fatal in young subjects, but it is equally true that its complications are frequently the cause of death. Rheumatic pleuro-pneumonia, associated with endocarditis and pericarditis, is a condition full of peril to life. The ultimate result depends largely upon the hygienic surroundings and social condition of the patient. As a rule, it is better in the child than in the adult. In a certain number of cases the signs of valvular disease ultimately disappear. In treatment, the first aim must be to cut short any rheumatic attack. Salicin and quinine sometimes succeed where the salicylates fail. Absolute rest in bed, entire freedom from excitement, and proper nursing must be continued week after week. The diet must be rigidly fluid, and given in small quantities, at short intervals. Stimulants may be required, sometimes freely. The disease runs an irregular course, sometimes extending from weeks into months. Such cases must be managed rather than "treated." Lack of firmness, patience and consistency in management, must too often account for the severity of some cases of chronic valvular disease.

(2) Period of compensation. Compensation occurs with exceptional completeness and rapidity in a child. We are constantly finding evidence of recovery in adults who are known to have had endocarditis in childhood. The first cause of interference with compensation is impoverished blood-supply from any cause. The second cause arises in connection with muscular exertion. Children sometimes strain a weakened valve at play, but this is rare compared with the damage which often occurs to the hearts of hard-working men. Neither are nervous influences so fruitful of evil in

the child as in the adult. The youthful subject of heart-disease must be faithfully watched. We must be on the lookout for symptoms of mental strain and at the same time see that muscular exercise is neither abused nor neglected. We must speak definitely as to games. Simple quiet cricket may be allowed, but match games of any kind, and violent games, like football, must be totally forbidden. Cycling would seem to be a safe form of exercise, but actual experience proves it to be dangerous from a tendency to over-ride. The subject of chronic valvular disease must be especially protected from rheumatism. The most trifling symptom of its approach must not be disregarded. From ten years to puberty is probably the most trying age. At that time the heart is especially susceptible, and in some cases requires constant attention; periodical examinations should be made, however free from symptoms the child may be.

(3) Heart failure. Symptoms appear only when compensation begins to fail. In several important respects they are peculiar to the child. Cardiac dropsy and albuminuria are infrequent. Pain is also less prominent, but dyspnoea is a constant and striking feature. Epistaxis is also frequent. Failure of compensation never arises without a cause. No attack of dyspnoea or palpitation should be allowed to pass without diligent search for that cause, for upon that the prognosis will largely depend. If it be muscular exertion, nervous strain, or injudicious treatment, a period of rest and correct treatment will restore the heart. But if rheumatism or other intercurrent disease is at work, the danger is great. On the whole, the prognosis of cardiac failure in the child is better than in the adult. When the more marked symptoms, as dropsy, occur, the prognosis is especially bad. Of the various new remedies and cardiac stimulants, there are a number of much value, but, on the whole, digitalis, if rationally employed, is the best. Strychnine, in a one-per-cent. solution of the hydrochlorate, used hypodermically, has in some instances an effect little short of marvellous in restoring the action of the ventricles.

## MITRAL STENOSIS IN CHILDHOOD.\*

The writer defends the opinion that obstruction at the left auriculo-ventricular orifice presents a most characteristic sound, the presystolic murmur. He gives a tabular report of twelve cases. He concludes that the congenital origin of mitral stenosis is not proven, but that its association with rheumatism is as definite as that which exists between regurgitation at the same valve and the rheumatic diathesis. This association is apt to be with a rheumatic condition that is not marked nor acute, but latent and insidious, in contradistinction to the severity of the attack in which the regurgitant murmur is usually produced. A murmur heard above and within the apex, that ceases abruptly with systole, immediately upon the apex striking the chest wall, or, with the finger upon the carotid, as soon as the pulse is felt, a murmur which, in a child, is usually harsh or rolling in timbre, and may commence immediately after the second sound and occupy the entire long pause, or may be audible only at the termination of this pause (the presystolic period, or, according to some, the post-diastolic), is, as we understand it, diagnostic of mitral stenosis. There are certain concomitant signs, such as

\* *Boston Medical Journal*, April 25, 1890. *Archives of Pediatrics*, January, 1891.

\* *Edwards: Philadelphia Medical News*, 1890, July, 1891; *Archives of Pediatrics*, February, 1891.

accentuation of the pulmonary artery second sound and seeming reduplication of the second sound, and the presystolic thrill. The largest proportion of cases is accompanied also by the murmur of regurgitation. There are dyspnoea, cough, and, later, local or general dropsy, delirium cordis, and tachycardia or cardiac distress. Others may present evidences of lesions in the nervous system, such as chorea, epilepsy, hemiplegia and localized palsies from emboli. The inherent power of the growing heart is usually sufficient to allow the organ to accommodate itself to the organic alteration, and in the absence of new invasions of the disease, to permit the child to attain maturity with a fair degree of health. In early life, it probably more often proves fatal than does regurgitation at this office.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. THE ONE HUNDRED AND TENTH ANNUAL MEETING.

BOSTON, JUNE 9 AND 10, 1891.

SECOND DAY.—WEDNESDAY, JUNE 10TH.

THE DINNER.

(Continued from No. 25, page 612.)

THERE'S one thing we're never tired of doing,—crowning Fair Harvard with the laurel, and hearing from that indefatigable worker in the cause of education, Charles W. Eliot, the President of the University.

PRES. C. W. ELIOT: You have given some proof, I think, that you are not yet tired of hearing me, for this is the twenty-second time that I have been invited to this festival. We may take the liberty of saying that from a medical point of view the State of Massachusetts still leaves a good deal to be desired. From a medical point of view, it is a disgrace that Massachusetts should be so far behind many other States of this Union in protecting, not the medical profession, but the poorer and least intelligent portion of the population against untrained and uneducated physicians and surgeons. The medical profession needs no legal protection, at least, not in this State. It can take care of itself. The persons that ought to be protected by Massachusetts are, as I have said, the poorer and least intelligent hundreds of thousands of her own population. Whenever you have occasion to present this matter to public men, to legislators and governors, always call for the protection of the people that are not able to protect themselves. It is not for you, it is for them, that we ask respectable legislation in the State of Massachusetts, to provide that no man shall practice medicine in Massachusetts who has not been fairly educated and trained to that end.

I am always happy on such occasions as this to have a chance to say something about education. In former meetings with you I have several times had occasion to testify that the means and methods of medical education need improvement, that they had been improved in some measure, but that they need still further improvement. I want to-day to dwell upon the opposite fact, now become true, that education in general is now greatly indebted to medical education for showing and putting in practice right methods of teaching, methods

which need to be adopted in all other walks of education.

Two great improvements in education characterize medical teaching during the last twenty years. One is the individualization of instruction. I very well remember the time, when I first knew about the Harvard Medical School, when the instruction consisted largely, almost entirely, in what were called didactic lectures—that is, general lectures, addressed to a large number of men; what I may call surgical exhibitions—that is, exhibitions of operations when but a small portion of the congregation could see anything really to their profit; and bedside instruction, where the number of pupils was altogether too great for careful instruction, for careful learning. Now these methods have all been infinitely improved. We see, in all good medical schools to-day, a great deal of instruction addressed to the individual. One medical student is taken in hand and shown what he must see, what he may find, what he should do, what he must learn to do himself. The teacher comes in contact with the individual pupil in the laboratory, in the dissecting room, and at the bedside and in each different department. This is a great improvement in medical instruction. It is the great improvement which is needed in all education—the coming down to the individual pupil by the teacher, the handling of that one individual case by the teacher.

Then there is another great improvement in medical education—the testing by acquired power, not by the memory, not by what a man can remember and reproduce orally or in writing, but by what he can do. Can you put on a bandage in this difficult fracture in the best way? Can you meet the emergency of a sudden and dangerous hemorrhage? Can you do it yourself? Can you set the dislocated hip when the thigh bone is broken besides? These are the tests of acquired power which every medical student must meet, should meet. Can you do these things yourself? There is no other adequate test of the merit of your training.

And that is precisely what all education needs. Education throughout all its branches, from the primary school through the university, needs always to be subjected to the test of acquired power, not of memory training, not of the storing of the mind with facts or even of principles. But it should be submitted to the test “what can you, the educated man, do?” And all liberal education has to thank medical education for greatly contributing to the introduction of these two essential principles into its own work.

Let me call your attention to another very important fact in the progress of education which the progress of medical education has brought strongly to mind. It is not more than a hundred years ago that medicine claimed to have been a liberal calling, an intellectual pursuit, and even to-day its position as such is very inadequately recognized by the mass of educated men. Now, I venture to say that, as medical education is now given in the best schools, no profession has a better right to claim the title of an educated, intellectual calling, and no men have a better right to demand recognition as intellectual men, as men of trained reasoning faculties, than the physicians themselves. I see, in my position at the head of the university, which includes the department of liberal arts and several professional departments, that the educated community does not recognize this. And I exhort you, gentlemen, in all your various fields of influence to do your utmost to establish this just claim of the medical pro-

fession to the position of an intellectual calling and to establish the claim of this great body as a body of highly trained men who use to the best advantage for the community the reasoning faculty, the scientific power of the human mind.

Letters of regret have been received from the following gentlemen: Dr. O. W. Holmes, Dr. H. I. Bowditch, Dr. G. B. Shattuck, Dr. J. S. Billings, of Washington, D. C.

#### THE MEDICAL PROFESSION.

Whatever may befall the other professions, — the clergy, the lawyers and the fighting men, — medicine is sure to go on forever. Men will fall sick till the crack of doom, and there must be doctors on hand to become a cinder like the moon, deserves a word or two cure them. A profession that will last till the earth on an occasion like this; and all will, I'm sure, agree that no one is better qualified to respond to this sentiment than Dr. J. Collins Warren, of Boston.

DR. J. COLLINS WARREN: I am glad to be able to speak for the medical profession, for the doctors do not seem generally inclined to speak for themselves. They are like the plumbers in one respect — they bear a great deal of abuse without saying anything in reply.

In looking back over some twenty-five years of professional experience, it seems to me as if a great deal of my time had been spent in defending myself and colleagues against the charge of bigotry and narrow mindedness, chiefly made by female members of the community, who seem to expect that we must accept and indorse with alacrity each new fad as it makes its appearance. One of the earliest of these that I remember is Spiritualism. I had occasion to look into the matter several years ago when preparing an address for this Society, and I was astonished to learn that there were at least a hundred thousand Spiritualists in Massachusetts, a great many of whom depended upon spiritual doctors for medical advice, and I was seriously entreated at that time by an intelligent gentleman not to lend my influence toward the passage of a law that would interfere with these practitioners and deprive many of his friends of the great comfort and consolation which could be derived from this source.

I will not attempt to enumerate all the various medical fads which have come forward and passed out of view during this period. I should not feel at liberty to encroach to that extent upon your time. It is certainly hardly worth our while to say much about homoeopathy. Whatever may be thought of the men who represent that sect, many of whom have received excellent medical educations, there are few of us who have given this matter any study who will deny that the practice itself, such as was expounded by its founder, has long since passed into history. My own experience is — and any of the prominent druggists in the city will doubtless tell you the same story — that our homoeopathic friends do not hesitate to avail themselves of all the resources of medical science when the occasion seems to demand it. I was much surprised to find that the number even of those who called themselves homoeopaths was exceedingly small in many States. Some States do not even enjoy the luxury of a single member of that persuasion. In conversation with a prominent practitioner of Hal-

ifax I was informed that there was but one homoeopath in the whole province of Nova Scotia.

A more amusing and much more modern fad, and one which may be regarded as the legitimate successor of Spiritualism, is the system of Mind Cure and Christian Science healing. I am frequently attacked — by my female friends again — with the somewhat specious argument that this mode of healing, if it fail to effect a cure, can certainly do no harm. My reply to this is that the danger lies not in the application of the method to a single case, but in the principle which allows a large class of persons to practise medicine with only a six weeks' medical education. None are so painfully aware of the difficulty of recognizing and dealing with the treachery of disease as those of us who have passed our lives in study. I, therefore, say to these ladies that the assistance which their money and influence may lend to such a dangerous fad as this is a direct menace to the well-being of a great many people. I would take this occasion also to remind them that the practice of medicine by ignorant persons is not without danger. In a case tried not long ago by the Commonwealth against an ignorant individual who undertook the responsibilities of a case which ended in the death of the patient, the Judge very properly stigmatized such conduct as "foolhardy presumption and gross negligence." I should not like to use such words in speaking of any of my female friends — it would not be polite — but would warn these ladies that unless they can show evidence of a reasonable amount of medical knowledge, they may suddenly find themselves in the very awkward predicament of this unfortunate man, who probably is still "doing time" in one of our State institutions.

I often hear the remark, that while we have made progress in surgery, the practice of medicine is still very much where it was fifty years ago. Nothing could be a greater mistake; for, although the medical men have not, at the present moment, the brilliant triumphs to boast of which surgery has, they may be congratulated upon having made great progress. The greater neatness and simplicity of the drugs used to-day are in marked contrast to the clumsy prescriptions of a previous generation. The introduction of the coal-tar products, including that valuable class of drugs known as antipyretics, and the possibilities of those mysterious compounds, the ptomaines, of which Koch's tuberculin is a conspicuous example, gives promise of a brilliant future to therapeutics. But it is not in this direction that the greatest improvements have been made. For all will acknowledge what a boon the advances in preventive medicine and the reform in the system of nursing is to the sufferer of to-day, and how it emphasizes the fact that the administration of drugs is but a small part of the modern method of dealing with disease.

The objects of this Society are not, I think, by any means properly appreciated by the public. We are looked upon by many as a sort of trades-union, a big and powerful corporation banded together for mutual protection. The Massachusetts Medical Society was originally founded to protect the public against uneducated practitioners. Its purposes are primarily to preserve a high standard of education among its members. This it has succeeded in doing, and it now maintains by rigid examinations a standard which insures to those who seek them the services of well-educated physicians. Attempts to regulate the practice of medi-

cine in this State have always excited violent opposition from uneducated practitioners, who have sought to persuade the public that it is an attempt on our part to take their practice from them. It is, of course, hardly necessary for me to repudiate this charge. My only criticism would be that our Society has not used its influence as it should in this matter, for who of us does not know from personal experience of the misery and unhappiness which the ignorant and unprincipled treatment of the sick has brought into many a household. What a record could be shown at the State House hearings could the victims be persuaded to tell their story! it is time that members of this Society should inform their respective senators and representatives of the urgent need of a move in this direction for the protection of the public health.

I have spoken, sir, a few words for the profession. I would not conclude without a word to the profession, especially to those young men whom I see around me, who are at the threshold of their careers. I would urge upon them not to forget how much good they can accomplish by the force of their example in maintaining a high standard of professional honor and integrity. They should remember that they have in their hands a weapon potent for evil as well as good. Let them beware lest, in the keen struggle of competition, they yield to temptation and strive to succeed by less honorable ways. And to those who find the world already at their feet I would also say: Scorn to retain your power by methods which are so easy to adopt, but which savor of practises which we ought to despise. Use your gifts to impress upon your clients frankly the true limitations as well as merits of the modern practice of medicine. And in his dealings with his fellow-men I would say to such a man remember, "Above all to thine own self be true, and it will follow as the night the day, thou canst not then be false to any man."

#### THE CLERGY.

After all the resources of the doctor have failed — and fail they will and must — we call in the physician of the soul. The clergyman is our coadjutor, and worthy therefore of a place at our board. I have the pleasure to introduce to you one to whom Shakespeare's lines aptly apply.

"A scholar, a ripe and good one;  
Exceeding wise, fair-spoken and personable;"

— Rev. John C. Brooks, of Springfield.

REV. JOHN C. BROOKS said that there was no other body of men in the community that knew life as did the clergy and the physicians. In the sick room they joined hands together, and there they had a common ground of meeting. The great bond of union between the two professions was not their successes, but their lack of successes, their failure to do what they wanted to do with human life.

#### OUR GUESTS.

The mitigation of pain and the prolongation of life are the chief results of medicine; but we frequently succeed in renewing the vision of the blind, and restoring the limbs of the cripple. Nay, some of us succeed in remedying the defects which Nature sometimes gives to the children of men. I have the honor to present to you Dr. V. P. Gibney, of New York City.

Dr. V. P. GIBNEY, of New York City, spoke very

briefly, simply expressing the pleasure it gave him to be present.

#### THE BAR.

Lawyers are the most versatile of men. One of their accomplishments is a knowledge of medicine, and they frequently know more about it than the regular practitioner — when the latter is on the witness-stand. We admire their ability, and welcome them to our ranks, especially when they've done us a good turn in the matter of medical legislation. I have the pleasure of presenting to you the Hon. Asa French, of Boston.

HON. ASA FRENCH said there was a strong bond of union between the bar and the medical profession, and their relations to the community were somewhat similar. Both were interested in ascertaining the right, both were rarely called in except as a last resort, and the first thing each had to do was to diagnose the case. Speaking of medical legislation, Mr. French said it was difficult to determine just what legislation could do. Something ought to be done. He saw no objection to the plan that Dr. Roosa had referred to as having been adopted in New York. That plan might possibly be modified by providing that a certificate or diploma from a school of medicine should be *prima facie* evidence to entitle a man to practice. However that might be, it was of the utmost importance, as President Eliot had suggested, that the community should be protected from "these pests of society." In closing, Mr. French paid an eloquent tribute to the memory of his life-long friend, now deceased, Dr. William G. Breck, of Springfield.

#### MEDICAL EDUCATION.

In these days of advance, of the multiplicity of special researches, medical education becomes a matter requiring the deepest thought and sagacity. To properly equip the licentiate, and at the same time save him from the waters of the deluge, is something to be determined only after long and profound consideration. Luckily, there are some who devote themselves to the question, and who are capable of affording the true light. I have the pleasure to present to you Dr. Thomas Dwight, of the Harvard Medical School.

DR. THOMAS DWIGHT: Believing, as I do, that medical education is always of interest to the practitioner, it gives me great pleasure to respond to this toast. Indeed, the present is a transition period of great importance, which has many features well worthy of your attention. In the first place, as you know, the Harvard Medical School announces that in the autumn of 1892, the medical course shall be four years. This has been the result of serious consideration, but we have not deferred taking the risk till generous friends should have made it certain that there should be no risk to take. I well remember the words spoken by President Eliot, if I mistake not, precisely twenty years ago, at this anniversary dinner, on the matter of the introduction of the three-years' graded course, — words which have come true once, and which will again: "The first step towards obtaining an endowment is to deserve one." Our admirable new building, and subsequent gifts, are the proofs. We are sure, should we suffer in our efforts to do our duty by the community still more fully, that the community, and especially the profession, will stand by us,

A very auspicious event is the formation of the Harvard Medical School Association, which with the guidance of its energetic president, will, I am sure, do all in its power to further the interests of alma mater. Unfortunately, it is not in the power of those who are Harvard graduates in medicine only, to exert their influence in one of the directions in which it is most needed,—in the choice of Overseers who shall recognize that the chief claims Harvard has to be called a University rest on the new graduate department at Cambridge, and on the professional schools.

And this brings me to that aspect of medical education which is now of the most pressing interest. The community may trust those whose business it is, to lay out a suitable course of medical instruction; but what concerns all, and what all must work for, is that without losing a college education students should begin their medical studies much younger than they do now. We meet with a very curious anomaly when we consider the career of such of our most favored young men as intend to devote themselves to medicine. It is strangely at variance with the popular idea of "young America" rushing into life crude and unprepared. We find the very opposite extreme. Entering Harvard at nearly nineteen, staying four years, he begins his medical studies at the age when in Europe, the more fortunate young man is nearing the end of his. Beginning then at twenty-three, I ask you to consider, even if no extra time be taken for life in hospital or foreign study, what chance there is of this man earning his living even as a bachelor, before thirty. But this delay in money-getting is not the only nor the greatest evil. A much greater one is the keeping back young men in the stage of pupilhood when their minds and characters should be profiting by the friction of active life. Few of the great men who have left their mark upon the world, began their activity after twenty-five. The over-long withholding of responsibility is a serious loss to almost any man who is to be more than a follower of others all his life.

What are we to do? Shall the future physician renounce the college course as too great an outlay of time? Many do so; and I am aware that I am speaking now to scores, if not to hundreds, who have achieved reputation, and substantial marks of success (not fortunes, for they do not come our way) without a college education. Yet could I appeal to these gentlemen, I do not doubt that most of them would wish their sons to go to college. A large part of the fault lies in our preparatory schools. The American young man does not know at eighteen or nineteen what he should. Undoubtedly, his natural ability goes far to counterbalance this disadvantage, but why should he be subjected to it at all?

The overseers, however grudgingly, have done something, and the college faculty show a disposition to make the most of it; but it is after all very little, though a step in the right direction. It is monstrous that a young man should not be ready at twenty, or at the latest, at twenty-one, to begin his professional studies. It is possible abroad; why should it not be possible here?

Thus, Mr. Chairman, is the matter which I wish to lay before this Society. The influence of this body is so reaching; its powers for good greater than we probably suspect. If the members of the Massachusetts Medical Society will study this question, and

put forth their influence, the cause of medical education will prosper.

DR. BRECK closed the exercises with the following:

Our banquet is over, our last toast delivered;  
Our festal board's empty; our throats are quite dry;  
The last flash of wit across us has quivered;  
The parting has come — good-night and good-by.

Good-by to you all — to every good Fellow  
From Maine to New York, or our own Commonwealth!  
May you never display the flag that is yellow,  
Or be other than sound and o'erflowing with health!

#### SECTION IN OBSTETRICS AND GYNECOLOGY.

DR. R. W. GREENE, of Worcester, read a paper on  
MODERATELY CONTRACTED PELVES.

By way of introduction Dr. Greene reported three cases:

CASE I came under observation at completed term. The patient was of American birth, aged twenty-seven. On inspection, pelvis symmetrical. Pelvic measurements as follows: anterior superior iliac spines,  $8\frac{1}{2}$  in., crest  $9\frac{1}{2}$  in., external conjugate  $7\frac{1}{4}$  in., internal  $3\frac{3}{8}$  in. Greater inclination of pelvis than usual; promontory of sacrum very prominent. Foot presenting; os admitted one finger; cervix little taken up. Pains of moderate severity and at long intervals. At the end of thirty-six hours, os fully dilated; pains not much improved in character or frequency; the patient fatigued and nervous. Under ether, the body easily extracted; but the head firmly held at superior strait. Child weighed  $6\frac{3}{4}$  lbs.; biparietal diameter  $6\frac{5}{8}$  in.

CASE II.—American lady, twenty-seven years old, average size. Previous labor lasted several days; delivery finally accomplished by craniotomy. Pelvic measurements: anterior superior spine  $9\frac{1}{2}$  in., crest 10 in., external conjugate  $7\frac{1}{4}$  in., internal conjugate (by estimate)  $3\frac{1}{2}$  in. to  $3\frac{3}{4}$  in. Labor induced at eighth month. A living child weighing  $6\frac{1}{4}$  lbs. was born. The mother's convalescence normal.

CASE III.—American lady, aged thirty-one, of average height and quite corpulent. A history of difficult and complicated labors. Pelvic measurements: anterior superior spine 11 in., crest  $11\frac{1}{2}$  in., external conjugate  $7\frac{1}{4}$  in., internal  $3\frac{1}{2}$  in. Labor induced at the thirty-sixth week. A female child born alive, weighing 5 lbs. 2 oz. Mother's convalescence normal.

Pelves of the flat variety and just-minor type, whose internal conjugate measured not less than three and three and a half inches respectively, came under this head. Many of the malpositions and difficulties arising in labor were due to contracted pelvis. When there was a history of difficult labors careful measurements should be taken. The condition of the mother, of the child, the presentation and size of the child, the patient whether primipara or multipara, whether at full term or not, would influence the treatment. The use of forceps, of version, of craniotomy, of Cesarean section and of premature delivery was considered. The reader held that the importance of the subject demanded more general study of pelvimetry. Second, that early resort to version was a safer operation for the mother than forceps when the head failed to engage at the superior strait. Finally, that in premature labor scientifically managed we had an operation by which an immense amount of suffering might be avoided, and oftentimes a living child secured.

DR. EDWARD REYNOLDS said that cases of flat pelvis were likely to be confined to the imported European peasants. Among American women, we would almost without exception have to deal with the justo-minor pelvis. The diagnosis between the two was of great importance, and the treatment radically and essentially different. The justo-minor pelvis was the pelvis of non-development, of arrest of development and the persistence of the infantile type; while the flat pelvis was the result of mal-nutrition, starvation, exposure and hard work from puberty. The flat pelvis had but slightly contracted external transverse measurements and yielded on palpation the sensation of comparatively ample transverse space of highly curved lateral walls; and the head being engaged at the brim, the hand found that there was a space between the forehead and occiput and the corresponding lateral walls of the pelvis. The head entered transverse and slightly extended. The pelvis, as a whole, was shallow, the sacrum highly curved, the promontory easily reached. On the other hand, the justo-minor pelvis was a long cylindrical pelvis, lateral walls straight. The head when engaged pressed with more or less equal force on all sides of the pelvis. The head entered oblique, and extremely highly flexed. The sacrum was long and straight; the pelvis, as a whole long; the symphysis long and erect.

In flat pelvis he thought version far the safer operation. On the other hand, he thought a justo-minor pelvis an absolute contra-indication for the extraction of the aftercoming head if it could possibly be avoided, and that forceps was far the preferable operation, the chief reasons being that the extraction of the aftercoming head not only was less successful in justo-minor pelvis on account of its being resisted on all sides by the pelvic walls, and on account of the necessity of maintaining extreme flexion in the mechanism, but because the narrowed transverse space rendered it unlikely that the arms could be extracted with sufficient rapidity to save the life of the child.

When confronted by a justo-minor pelvis with a breech presentation he should attempt to perform external version early in labor in order to secure a well-flexed head, and apply forceps in preference to being obliged to perform the usually extremely difficult and he thought, generally hopeless task of attempting to extract a living child from a justo-minor pelvis.

He thought the general principle most valuable for men not especially trained in pelvimetry was to assume that the American-born woman whose pelvis was contracted had a justo-minor pelvis, and that it was better in a head presentation to use forceps instead of version. If, however, the physician was led to believe that he was dealing with a flat pelvis with fair or ample transverse space, he thought it better to consider version the election of choice, and make the application of forceps, if he chose to resort to it, merely a tentative matter to be abandoned unless successful, and succeeded by version.

The question of Cesarean section it seemed to him rarely came up in this class, because under modern aseptic methods, the induction of labor was so uniformly successful for the mother, and also for the child.

DR. WHEELER said the rules laid down by Dr. Reynolds could not serve for our entire guidance. We could not divide patients into Americans and not Americans. Some were half Americans and part some-

thing else, and we had all sorts of pelvis between, and his rules did not help us out in the management of women of foreign birth, for there we had the various kinds. It seemed to him that the measuring of the pelvis ought to be just as much a part of the obstetrical education as anything at all except antiseptics.

There was an interesting point in connection with one of the cases of which Dr. Green had spoken. The woman had had eight pregnancies, with four births of children at term. Two of them were breech, and three were forceps deliveries of the head, two of which he (Dr. Wheeler) delivered with Tarnier forceps, the head just engaging, and in the first one there was a fracture of the skull of the child where it passed over the promontory.

In a case with such a previous history it seemed to him that there need be very little hesitation about the induction of premature labor. It could be done with almost absolute safety for the mother, and the prospects for the child were exceedingly good. But with primipara he did not see how we were to treat such cases, unless we adopted the rule of measuring every pelvis previous to labor where we had any knowledge of the patient previous to being called to the confinement.

DR. C. M. GREEN said that in the American women we did not get the great contractions of the pelvis, and his experience had been that we did not find the small flat or rachitic pelvis, but did get the justo-minor pelvis from non-development. The treatment one would adopt at any particular time, of course, would depend largely on previous experiences in childbed. With the primipara the pelvis had got to be measured at the time of confinement, and the appropriate treatment selected.

The difficulties of pelvimetry were sometimes so great that no satisfactory measurement could be made at the time of labor, so that one had to do the best he could for that pregnancy. The pelvis could be carefully measured afterwards, and in the event of subsequent pregnancies a premature labor might be induced, or the patient allowed to go to full term and then have version or forceps or Cesarean section, according to the degree of deformity.

We divided pelvis into the flat and the generally contracted. He had no question from experience and trial that high forceps gave better results in the justo-minor pelvis than version. The mechanism showed that. If he were to deal with such a case, the breech presenting, he should turn the child about by external version and convert it into a head case, and deliver by high forceps.

In the simple flat pelvis where the contraction was chiefly, if not entirely, in the antero-posterior diameter; unquestionably, in most hands the operation of internal prolific version would give better results. In such cases it was not the biparietal that came through the conjugate, but the head passed through, probably by the bitemporal diameter, and there was ample room in the transverse. He had a feeling, however, that the time would come, as men became more and more expert in the use of forceps, when the forceps operation would very likely be more commonly practised than version in even the flat pelvis. He was led to think so by the result of some experiments, namely, that compression of the head in the antero-posterior diameter did not enlarge the transverse diameter but that the head simply elongated. It was, however,

safe to remember that high forceps operation was on the whole more dangerous to the mother than version, except in very skilful hands; so that he felt that one ought not to hastily resort to high forceps unless he had carefully considered the case, and regarded himself at least moderately skilful in the use of the instrument.

#### PESSARIES: THEIR USE AND ABUSE.

Dr. C. M. Green, in opening the discussion, called attention to the definition of the word pessary as given in "The Century Dictionary," namely, that it was an instrument made in various forms of elastic or rigid materials, and worn in the vagina to remedy various uterine displacements. He hoped to impress upon the section the fact that the pessary was not an instrument to remedy a displacement. He would give the following definition: that it was an instrument made in various forms of elastic or rigid materials, and worn in the vagina as a splint or crutch to hold as near as may be in normal position the uterus and incidentally the ovaries and vagina in some instances after these organs have been restored to their normal relations.

In case of prolapse of the uterus, where the prolapse was of the first degree or slight, he did not use a pessary, but endeavored to diminish the weight of the uterus, which was heavy perhaps from subinvolution, by the use of the hot douche, of tonics, etc. It was sometimes necessary to use pessaries in hard-working women, since they could not conform their lives to the requirements of the best treatment for such cases. Dr. Green spoke briefly of the various forms of uterine displacement in which a pessary might prove useful, and exhibited various pessaries which he was in the habit of using.

It was an abuse of pessaries to use any form of hard pessary before the uterus was in its normal position, or when there was present any inflammation in an active or semi-active condition. There were cases, however, when the second condition was absent in which he used a pessary in order to allow of the use of the hot douche. Sometimes he had found that after stretching adhesions and getting the uterus partly up, there being no tenderness, a lever pessary of the proper shape and size could be safely used, and the vaginal douche employed.

Dr. Green, in closing, spoke at length of the importance of seeing to it that a pessary is properly cared for. He thought it should not be used in patients not sufficiently intelligent to realize this. It was important to have patients return at stated times in order to inspect the parts to see whether the pessary had produced any disturbance, and also to see whether the pessary had been well cared for and was in proper position.

Dr. E. REYNOLDS found that with increasing experience he used pessaries less and less, not only on account of the danger of the abuse of the pessary by the patient's own neglect, but essentially and primarily on account of the belief that displacements of the uterus were not in themselves disease. They were the physical signs of pathological conditions of which pain and exhaustion were the subjective symptoms. Where there was a displacement of the uterus, it was either because the uterus was too heavy or the supports were failing in their office. Under those circumstances the use of a pessary was a temporary palliative to be used while we were adopting other means of treatment for the radical cure of the essential diseased condition.

When confronted with a displacement we thought needed treatment we ought to be careful in every case, after the displacement had been reduced and the pessary inserted, to attempt to discover the reason why that uterus became displaced and to correct, if possible, that essential primary condition. It might be that the uterus was heavy from subinvolution, from extreme congestion, passive or active; or that some solution of continuity after child-birth had destroyed the efficiency of the parts, or that the supports had lost their muscular tone in debilitated women.

No one should regard the pessary as curative, but simply as a temporary expedient. He thought that the pessary should be used only in intelligent patients, and that the patient should be made aware of the dangers of pessaries, and the absolute necessity of having them inspected frequently. His own rule was to direct every patient to come after her catamenia each time, have the pessary removed, washed, and, if necessary, changed.

As regarded the choice of pessaries, he did not believe the routine use of pessaries made by instrument-makers was to be adopted. The hard rubber pessary could with a little care be easily moulded. He thought it essential to make the pessary small. It was surprising, when one learned to use a pessary so small the finger would pass on all sides of it, to see how efficient it was and it was surprising to see how the percentage of injuries from pessaries had dropped when one learned to use a small pessary which was retained in position not by exerting pressure on surrounding tissues but by adaptation to the shape of individual organs. He thought it important, also, not to make the upper arm of a lever pessary too long or too highly curved. In his own experience the chief injuries had come from over-long and over-highly curved arms of lever pessaries.

Anterior displacements, in his opinion, also very rarely needed treatment.

As regards the abuse of pessaries, he thought that a great many of the nervous troubles of women which arose in single women or widows from ungratified sexual desire primarily, were often rendered very much worse by the insertion of pessaries. The point was prominent in his mind from having seen two or three cases in the last six months in which neurotic women had been maltreated by the use of pessaries, which they confessed themselves kept them in a state of continual excitement; and he thought every one should estimate the nervous system of a woman in that respect before he inserted a pessary, though he thought such a result was due to the insertion of a too large pessary, and would not follow the use of a properly fitting pessary.

Dr. WHEELER said there was a degree of mystery attending the use of pessaries owing to a lack of knowledge of the anatomy of the pelvic contents. It was only within a few years that Schultze's picture of the normal pelvis found its way into our text-books, and that was the first one that was right. If we had that in mind it seemed to him that the trouble in the very much vexed question of anteversion and flexion quite disappeared. One could not have an abnormal anteversion or flexion without surgical operation. The uterus lay flat on the anterior vaginal wall except that the filled bladder lifted it off. It could not antevert any further unless one did something to get rid of the anterior vaginal wall. If one got the anatom-

ical idea, then the use of the pessary was founded upon something other than empirical rules.

The size of the pessary seemed to him a most important consideration. The temptation was always to use the pessary too large. The number and kinds of pessary that he used was very small. For something to fill the vagina for a prolapse he used a hard rubber doughnut pessary oftener than the one Dr. Green showed. There again the smallest one that would stay in place was the best; but it was unscientific and to be used only where operation could not be obtained.

Dr. MERCER said there were cases of prolapse in old people that no form of pessary exhibited by Dr. Green would fit. Such cases could not submit to operation and operation indeed would be of very doubtful value from the long continuance of the displacement. He had found the large-sized globular form of cup with the abdominal belt and elastic band very satisfactory as a means of relief in these cases.

#### A CASE OF TRIPLETS,

by H. F. VICKERY, M.D.

On April 14, 1891, I was called to see Mrs. H., a native American lady twenty-six years old, whose last catamenial period had occurred September 21st to 27th. Marked oedema of the lower extremities and walls of the abdomen, some puffiness of the hands. The swollen flesh had a translucent look suggesting either a disturbance of the heart or more likely the kidneys. The urine contained a trace of albumen, and a considerable number of hyaline and finely granular casts, the specific gravity being 1.020. The heart seemed normal. The abdominal walls were very tense, and palpation did not enable me to discover any fetal parts, nor upon careful auscultation was I then, or at any subsequent time, able to hear a fetal heart. On digital examination, I felt a fetal head presenting. The patient complained of recurrent uterine pains. Under treatment the pains diminished, and the amount of urine reached three pints with a specific gravity, however, of merely 1.008.

On the morning of May 9th, I was summoned because spontaneous rupture of the amnion had occurred. This was on the 224th day after the cessation of the menses. I found the patient, who is a slight woman, very edematous, the abdomen extremely distended, the vulva so swollen that examination with a single finger was very painful to her and difficult for me. It was a vertex presentation. Fearing the supervention of eclampsia I gave at intervals of fifteen minutes three doses of fifteen grains of chloral, and also of bromide of sodium, some seventy grains in all.

The dilatation of the os was tedious, for the womb seemed too distended to contract forcibly, and moreover the bag of waters had been ruptured. Toward noon, however, the pains in spite of the chloral had become very trying to the patient, and ether was now administered during each pain, but not to the point of narcosis. At two o'clock of the same afternoon the os had dilated almost completely, and lest the patient should become exhausted, and also for fear of convulsions, I resolved to empty the womb. Under complete anesthesia the forceps brought easily into the world a female child; but after its birth the womb was still much distended, and an amniotic sac was found presenting at the os through which a second vertex could be felt. Upon the rupture of this bag,

however, a pair of feet enclosed in a third sac displaced the head. This third bag being ruptured and a second little girl easily delivered, the third child, also a female, was extracted with the forceps, the occiput being posterior (face to the pubes). As the placenta did not come away readily, and I feared to prolong the anesthesia, I introduced my hand into the womb and withdrew a very large placenta. The edematous tissues of the vulva were slightly torn. This seemed to be due more to their pathological state than to the size of the children or any undue haste in delivery.

The mother's convalescence was favorable, although she has not yet at the end of a month recovered her full strength.

The three little girls were perfect in every way, and each weighed four pounds. The mother's ordinary weight before marriage was one hundred and five pounds. But one of them developed any propensity for nursing, and it was necessary soon to put her upon artificial diet as the mother's milk proved very scanty and soon disappeared. Although very urgent advice was given with regard to keeping the children continuously warm, they were more than once allowed to become chilled, and from the time of one such occurrence the second of the triplets seemed permanently weaker, gradually failed and died on the 22d day after birth. For the last fortnight the little ones, including this weaker one until she died, have been kept in a large uncovered square box very thickly padded with cotton, and containing three large hot water bags which are changed once in three hours.

The diet has been Anglo-Swiss condensed milk put up in Switzerland, one part; lime water two parts; plain water nine parts, and with the addition at each feeding of one drop of pure cod liver oil. The children have not vomited; they have not seemed to suffer from colic, and their stools have been fairly normal.

In January, 1890, C. M. Green<sup>2</sup> of this city, reported a case of labor with triplets at full term in which a diagnosis of multiple pregnancy and possibly a case of triplets was made by a student of the medical school before delivery, but in the case which I have reported, it does not seem to me that any positive diagnosis could have been made, but only an inference based upon the disproportionate size of the abdomen, and this I felt at the time might be due to an ascites having added itself to the pregnancy.

#### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

REGULAR meeting, Wednesday, April 22, 1891, Dr. E. G. CUTLER in the chair.

Dr. G. W. ALLEN reported

#### CASES OF RENAL COLIC.<sup>1</sup>

Dr. PUTNAM: It is often very hard to tell whether the pain in these cases is due to some organic cause, or is simply neuralgic in character; and this is also true of cases of neuralgia from gall-stones. It is cer-

<sup>1</sup> See page 627 of the Journal.

<sup>2</sup> Boston Medical and Surgical Journal, vol. cxlii, p. 245.

tainly true that one may have passed gall-stones and be unable to find them, and have no jaundice, but simply the neuralgia, and yet the case may turn out to be one of organic disease.

DR. J. J. MINOT: I think a common cause of these pains was omitted by Dr. Allen, that is, one due to movable kidney. I have seen several of these cases, and the pain is exactly like it. It is not always possible to find the kidney during or immediately after the attack.

DR. WITHINGTON: I spent a few hours last night with a gentleman evidently suffering from renal colic. The attack began on Monday of last week, and it seemed at first to be intestinal trouble, because the location was not possible to be made any more definitely, and the urine at that time was negative. He had morphia Saturday, none Sunday; Monday he had a good day. The urine passed after the onset of attack contained a number of evidently uric-acid crystals. The pain was in the left flank at first, and afterwards, leaving that place, was at the left and below the umbilicus. It was controlled with great difficulty by morphia. It returned again this morning and has been more permanently controlled by large doses of morphia. The appearance of uric-acid crystals in size to be recognized by the naked eye, was interesting.

DR. J. J. PUTNAM read a paper on

#### THE CHARACTER OF THE EVIDENCE AS TO THE INJURIOUSNESS OF ARSENIC AS A DOMESTIC POISON.<sup>2</sup>

PROF. J. M. CRAFTS: The question has been put before us so clearly with indications of the possible development of its experimental side by Dr. Putnam, that it has excited very great interest, and I can only go on and make some suggestions as to still further experiments that can be made.

There was one remark made in reference to the analogy between phosphorus and arsenic compounds. Chemically the two substances are more or less analogous. The highest products of oxidation, namely, phosphoric acid and arsenic acid, have similar formulae. If there is any analogy to be followed out it would not indicate that arsenic acid is more poisonous than arsenious, but the contrary. Phosphorous acid is very distinctly poisonous, and compounds of phosphorus with hydrogen are notoriously poisonous. One can scarcely conceive any reaction going on in the tissues which would transform arsenious into arsenic acid. Arsenic acid is quickly reduced to arsenious acid, and I should suppose if arsenic acid were used it would quickly be reduced and the poison act in the form of arsenious acid. The fear of poisoning from arseniuretted hydrogen has, I think, been exaggerated. Some published remarks have hinted at poisoning by imponderable quantities. I don't think we need go so low as imponderable quantities. Every chemist has breathed appreciable quantities of arseniuretted hydrogen.

As to the possibility of arseniuretted hydrogen being formed in wall-paper it is the business of the chemist who thinks that may be the *modus operandi* to see if he can get it from the wall-paper. So far as I know, no actual evidence of this has been secured.

In reference to the statements of the possibility of arsenic accumulating, there has been raised an extremely important point which probably will remove a great many of the objections. Physicians are in the

habit of administering Fowler's solution, one drop three times a day as a minimum dose. A drop would be considered a grain, and Fowler's solution is a one per cent. solution, consequently that makes three hundredths of a grain, and that is about three times the amount eliminated through the urine. Let us take a wall-paper containing one grain to the yard, which would be considered too much charged with arsenic to use it. Suppose there are about fifty yards. If a great deal of the coloring matter comes off, the paper is degraded in quality and would be changed. Suppose we estimate that one-fifth of the coloring matter comes off. That would make ten grains of arsenic during the duration of the paper, that might come into the air of the room. The duration of the paper certainly would be ten years before it would be changed, so that that would make one grain per year, and every day the possibility of the contamination of the air of the room by one three-hundred-and-sixty-fifth of a grain, about one-tenth the dose in Fowler's solution. That would be on the estimation that all the dust from the paper would be breathed into the lungs. That is not the case. I do not wish to insist upon that, I only wish to suggest this much on its experimental value. The ordinary inhabitants of a room I think are not very much exposed to poisoning except in very special cases or cases of extreme susceptibility, but there are certain inhabitants of houses whose business it is to stir up the dust, that is, the house-maids. The house-maid would breathe many times the dust of the inhabitants, and it would be worth while to notice whether the cases of arsenical poisoning are particularly to be found among the house-maids. The dust of chimneys is full of arsenious acid. Where the ordinary dweller in the house would breathe one one-hundred-thousandth of a grain, the chimney-sweep would be exposed to breathing several grains of arsenic, and I don't know that physicians have been led to think that the occupation of the chimney-sweep was an insalubrious one to be regulated by law.

A source of contamination with arsenic recently pointed out is from coal. When coal is burnt it is roasted out and it is the only product of the coal which is at first volatile, and afterwards non-volatile. A part of the smoke that goes into the air is arsenious acid mixed with carbon, and a large part of it lodges in the chimneys. Now take a city like London or any of the great English cities where coal is burnt very freely, there the quantity of arsenious acid that is given into the air must be very considerable, and it would be interesting to make comparative tests of the urine of persons in a city like Boston and in a city like London. The English coal is very bad coal in this respect. Every ton of coal burns off about twenty to forty pounds of sulphur. That sulphur is transformed into sixty pounds of sulphuric acid which has left its stain on every marble building in London. I speak of the sulphur because the sulphur is largely accompanied by arsenic.

I am heartily in favor of some form of law which would restrict the sale of arsenic. What interests us here is the possibility of conducting further experiments and getting more light on this very interesting subject, and I should suppose the line of investigations suggested by Dr. Putnam would lead to extremely interesting results.

PROF. H. B. HILL: In view of the facts already well established, the explanation of the mode of action

<sup>2</sup> See page 623 of the Journal.

of the arsenic contained in arsenical wall-papers, seemed to me to possess subordinate interest. Dr. Putnam had thought that the chemical evidence rendered it improbable that gaseous compounds of arsenic were formed. The chemical evidence, however, seems to be unsatisfactory in that all experimenters had used substantially the same method, and that one which was open to criticism. Here, also, the clinical evidence seemed more trustworthy.

There was one thing in Dr. Putnam's paper that interested me especially, and that was the rather reluctant admission he made, based on Dr. Sanger's work, that no gaseous compound of arsenic probably was formed with arsenical wall-papers. Of course this subject has been investigated very thoroughly by a great many men in the last twenty or thirty years, and yet I believe hardly two of them have taken precisely the same method.

Dr. Putnam published a year or two ago an account of twenty-five interesting cases of poisoning by wall-paper, in three of which he traced the source of the poisoning to an arsenical paper which was covered by a non-arsenical paper, and no other arsenic was discovered in the environment of the patient. It seems to me extremely difficult to explain poisoning under these circumstances, arsenic being found in the urine in each case, and disappearing after the arsenical paper was removed. I have myself seen in the last three years, I think, two such cases. In both of these cases we found arsenic in the urine. It turned out after long search that the bed-room of the patient contained arsenical paper that was almost harmless. After four or five months I found the urine free from arsenic. In the last few months a similar case was sent to me. The paper was removed from the wall and the patient is now decidedly better. It seems to me, under these circumstances, the physiological evidence is much more convincing than any chemical evidence that has been brought forward, and it seems to me the essential difficulty thus far has been that the whole delicacy of the method was brought down to the power of the nitrate of silver to absorb the arseniuretted hydrogen. I think it is not a rash assumption to make that nitrate of silver cannot be much more active an agent in absorbing arsenic from air than sulphuric acid is for water, and yet sulphuric acid would leave twenty minims of water in twenty-four hours. Why should not nitrate of silver leave arsenic?

Many wall-papers are brought to our laboratory by prudent people for analysis, although they have suffered no ill-effects. Some of the papers are found to be highly arsenical, and they are advised to remove them; and some are found practically free, and they are advised to keep them on. There are a number of them containing a considerable amount, and I am asked would it not be well to cover these. It is a matter of considerable practical importance to many people to know whether they are obliged to take their papers from the walls entirely or cover them. I have usually advised them not to cover them. In cases where poisoning is well-marked, I always look out for the under paper as well as for the one at the surface.

Dr. KNAPP: I feel that I must come rather as a learner than one who can contribute much. We are all of us indebted to Dr. Putnam for the very thorough and exhaustive work he has done, and for the efforts he has made before the legislature. I can bring forward almost nothing from my own experience that would

have any practical bearing on the question, but I will simply say that in the last month I have had Dr. Wood examine the urine in three cases that have come to me, and in two of them there was a large amount of arsenic, and in the third a trace. The symptoms in both cases were rather characteristic, leading me to suspect arsenic. One of them had had numbness of the face and extremities and weakness, general mental depression, and anamia extending over a period of two or three years. She was a clerk in Loughton & Dutton's, where she had charge of the department where there were colored cloths, etc. In that case I have not as yet got specimens of the wall-paper, but I have no doubt there is arsenic in the wall-paper of the house. The other case was a lady who had had symptoms for several years, and several of the wall-papers in her house, and the water-color of the frescos in her bed-room were pronounced dangerous by Dr. Wood.

In regard to the question of the chemistry and of the elimination of arsenic I can contribute nothing. It is probably a little out of order, but there is a very curious resemblance between the statements of the New York chemists on the subject of arsenical poisoning and those of the New York electricians on the subject of electricity. Some of the New York electricians claimed that electricity was perfectly harmless, and that no one could be injured by it. According to New York chemists arsenic is a thing used by physicians, it is rather beneficial than otherwise, and arsenical poisoning is only a Boston fad.

Dr. PUTNAM: I think the suggestion of Professor Crafts in regard to investigating certain classes in the community is a very important one. I had already thought of doing it in regard to the coal-heavers.

I entirely agree with Professor Hill in saying that the clinical evidence seems to be the important thing after all. We find patients with arsenic in the urine, and it seems to me that that is a valuable aid to us. It shows not only that a certain exposure has occurred, but that arsenic has been absorbed. I think, finding it there and finding symptoms, we are more at liberty to say that certain symptoms are due to arsenic than if the symptoms existed and arsenic did not exist in the urine.

The fact that we cannot tell how a person gets poisoned, should not lead us to conclude that he could not have been poisoned. I dare say too much has been made of the idea that a special paper was the offending source, when perhaps a portion of the arsenic came from other sources. At any rate, I think it happens comparatively rarely that a single paper is really the only possible source of arsenic. One case came to my knowledge where the patient had an acute inflammation of the skin of the face, of peculiar character. In that case the scales in the skin were found to contain a small quantity of arsenic and the urine contained it. If that patient had been exposed to an arsenical wall-paper it might have been supposed that the wall-paper was the source of the arsenic, whereas in fact this patient was in the habit of leaning upon a reclining chair the cover of which contained arsenic.

The matter of susceptibility is very important. One of my colleagues has been poisoned several times from stuffing birds. He has lately had edema of the eyelids and conjunctivitis following exposure to arsenical wall-paper, which disappeared upon the removal of the paper, and he was the only member of the family affected.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, JUNE 25, 1891.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

# INSOMNIA OF GASTRO-INTESTINAL ORIGIN.

WRITERS have dwelt much on the cerebral hyperæmia attending disordered states of the stomach. That indigestion causes insomnia by exciting the cerebrum is a matter of common experience. With many persons, even, the active exercise of digestion, if this be at all dillicult, is incompatible with sound sleep. Such individuals refrain from lunching or partaking of a hearty meal before going to bed. Certain valetudinarians cannot drink a glass of milk or eat a biscuit late in the evening without atoning for the indiserision by hours of sleeplessness.

Such inhibition of the cerebrum by the stomach is of frequent experience in the nursery. The first thing the physician thinks of when consulted with reference to insomnia in a young child is the probability of indigestion as the main factor in the case. What is the quality of the food, what about the quantity, and what is the condition of the digestive organs? Attention to these points, in the absence of objective signs of importance as fever, will generally put one on the track of the cause and suggest the remedy.

The indigestion may be functional or organic, and all pathological conditions of the stomach are likely to be accompanied by insomnia. Structural diseases, as gastritis, ulcer, gastrectasis, cancer, cause sleeplessness, both by the pain and discomfort, and the consequences of indigestion which attend them. One of the most frequent symptoms of indigestion is flatulence. The stomach, by failure of the normal peptonization process, is inflated and oppressed by the gases of decomposition; the distended stomach presses on the thoracic organs, embarrassing the heart and causing troublesome palpitations. Toxic products are often formed by the mal-elaboration of peptones; these irritate the nervous centres and render the cerebrum hyperæmic.

But there is another aspect of the question. In persons with healthy stomachs and normal arterial tone, the digestive process is not prejudicial to sleep. Somnolence, in fact, often attends digestion, especially after a hearty meal. This has been attributed to the

flushing of the stomach — at the expense of the cerebrum — which is a necessary condition of its function. Digestion normally occurs without attracting the consciousness, and there is no reason why on proper occasions sleep should not follow a hearty meal in men as well as in carnivorous animals. It is not true that during sleep the digestive functions are practically suspended, as some authorities have said: "During sleep the medullary centres relax their activity, digestive fluids are not secreted, and the movements of the gastro-intestinal canal almost, if not entirely, cease."<sup>1</sup> It is surprising to meet with an error of this kind in a writer ordinarily so accurate as MacFarlane. The stomach and intestines continue their function during sleep, though with lessened activity; the secretions are not suspended, the unstriped muscular fibre continues a constant though diminished action; the spinal cord even seems preternaturally active, the inhibiting restraint of the cerebrum being withdrawn. In reality, in sleep all the essential functions continue to be exercised. Those most indispensable to life, circulation, respiration, digestion, etc., are performed as during the waking period, though more sluggishly. Thus, the heart beats more slowly during sleep. "*Pulsus in somno parvi, languidi rari*," says Galen. With the retardation of the circulation, there is diminished activity of the secreting glands (gastric, intestinal, pancreatic, etc.), but in healthy persons these organs are adequate to the work imposed upon them, as is proved by the fact that multitudes can eat a full meal on going to bed, sleep soundly, and be ready for another meal on awaking. Nor can it be said that the peristalsis of the gastro-intestinal canal ceases during sleep, any more than the contraction of other unstriped muscles (the arterioles, for instance), which are not under the will.

Germain Sée, who refers most cases of digestive insomnia to difficulties attending the secondary or intestinal digestion (and here he is seconded by MacFarlane) thus defines this kind of insomnia: "Intestinal digestion generally begins three hours after a meal and ends in seven or eight hours. The patient, we will suppose, sups at 6 o'clock P. M. At 10 o'clock, he goes to bed, but cannot sleep till long after midnight. This is the time when the pancreatic-intestinal digestion is going on; when this is finished, the patient goes to sleep.

"To prove that I am right as to the cause of the insomnia, let the patient eat a light supper at the usual time, or let him sup at 4 o'clock in the afternoon, and he will find that he will go to sleep at the proper time."<sup>2</sup>

In the treatment of insomnia from indigestion, the quantity and quality of the food must be taken into account, the condition of the stomach, intestines, and the auxiliary organs.

(1) Errors are most frequently committed as to quantity. The digestive organs may be competent to dispose of a certain bulk without pain or difficulty,

<sup>1</sup> *Insomnia and Its Therapeutics*, p. 192.

<sup>2</sup> *Des Hypnotismes*, etc., Second edition, Paris, 1883.

while an excess causes embarrassment to the stomach; decomposition and flatulence set in under unmolested microbial rule; putrid and more or less toxic gases and ptomaines are generated, and a "bilious" condition supervenes, such as every one has experienced at times. It is doubtless true that while multitudes are underfed, more persons are injured by excessive eating than by a spare diet. Insomnia naturally comes in as one of the consequences of over-eating and over-drinking, for a burdened stomach will not let the brain rest.

The proper remedy for sleeplessness arising from this cause is apparent: it is to curtail the daily rations to the physiological standard. The necessity of eating slowly and deliberately with thorough mastication of the food, is apparent; those that "bolt" their food are sure to eat to excess.

(2) Food of poor or insufficient quality produces anemia and starvation of vital organs, including the cerebrum, and hence engenders insomnia. Physicians cannot too much insist on the necessity of a full diet, that is, of an adequate admixture in the daily fare of albuminoids, fats, and carbo-hydrates. Food of indigestible quality, produces essentially the same evils as excessive alimentation. Under this head may be included food improperly or insufficiently cooked (good cookery under our civilization has become indispensable to healthy digestion), and foods that most persons of sedentary habits find hard to digest, as unripe fruit, pastries, hot bread, fried pork, confectionery. Of course, butcher's meats should be selected that are tender and juicy, and in the light of recent discoveries (Gautier, Selmi, etc.), it is doubtful if meat or game that has become high (*faisandé*) is fit for food.

Foods of themselves sufficiently digestible may become indigestible if too many kinds are eaten at a meal. But this brings us again to the evils of excessive eating.

It need not be repeated that he who would sleep well must avoid those articles of diet which have been found to be indigestible, or should indulge in them sparingly. Much depends, of course, on the muscular work done. Horace speaks of the *dura illia messorum*. The hay-makers on the salt marshes need food hard of digestion, that is, food that is *slowly* digested, yielding up force for many hours; food that in common parlance "stays by," such as baked beans and pork, boiled beef and cabbage, and mince pie. Such persons sleep well, despite their hearty fare; it is especially the "brain-workers," the men of sedentary habits that are upset by a rich diet.

(3) A healthy digestion presupposes a healthy state of the stomach, intestines, and accessory organs, and any derangement of these viscera must be corrected by suitable medicinal and dietetic means before normal sleep can be enjoyed.

To enter on a consideration of all these derangements, would take more space than we have at our command. The hygienic treatment of indigestion includes dieting, exercise, recreation, cold bathing, etc. The cold shower-bath in the morning is sometimes a power-

ful aid to digestion. Exercise promotes a more vigorous circulation and favors peristalsis and chymification; equally necessary are change of scene, diversions, and the cultivation of a contented, cheerful frame of mind.

Among the medicinal means are:

(1) Such as favor gastric digestion, namely, alkalies before meals, and acids with pepsin, after. Clinical experience has proved pepsin to be of some value. Small doses of strychnine are useful.

(2) For acid dyspepsia full doses of bicarbonate of soda are naturally indicated. Professor Sée advises dyspeptics with excess of acid secretion, to take a drachm of bicarbonate of soda in hot water on going to bed. It is certain that in certain morbid states of the stomach and intestines, whether due to "*hyperchlorhydria*" or to excess of mucus, the beneficial sedative effects of alkalies are pronounced.

(3) Constipation is another recognized cause of insomnia, whether by the reflex irritation of retained excreta, or by the flatulence which frequently attends a loaded colon. Here the remedy is obvious: such laxatives as rhubarb, Glauber salts, cascara, enemata of hot water, etc. Persons who sleep poorly from this cause often find a hot water enema on going to bed a sovereign remedy.

When that old bugbear, a torpid liver, is at fault, (if this can be determined), of course a blue pill, a dose of enonymin or podophyllin would seem to be indicated.

There is an acidity of the stomach which depends on abnormal acid ferments, the products of decomposition of starches or sugars in the food. In these cases, washing out the stomach by means of emetics and copious draughts of warm water every night for three or four nights, as MacFarlane recommends, often proves very efficacious. The same writer advises ferro-alumen in three-grain doses for pyrosis along with three drops of dilute hydrocyanic acid, and turpentine in ten-drop doses for flatulence, as most effective remedies.

#### MEDICAL NOTES.

TULANE UNIVERSITY. — The medical department of Tulane University, New Orleans, has received a gift of \$100,000 from Mrs. T. G. Richardson, which is to be used for the erection of a new building.

THE METRIC SYSTEM. — The American Pharmaceutical Association has instructed the proper committee to memorialize Congress to adopt as the governmental standard the metric system of weights and measures.

GERMAN CONGRESS OF INTERNAL MEDICINE. — The following subjects have been proposed for discussion at the next meeting of the German Congress of Internal Medicine, which will be held at Leipzig in 1892: The Physiological and Therapeutical Value of Iron, Meningitis in its Different Forms, Electrotherapy, The Treatment of Severe Pneumonia.

**SAHARA AS A HEALTH RESORT.**—It is reported that European invalids and other persons in search of quiet and a mild climate for winter are beginning to turn their attention to the oases on the northern border of the great Sahara, where the climate is very equable. Railway communication through Algeria makes these places less inaccessible than formerly.

**MINERAL WATERS NOT LIABLE TO DUTY.**—One of the questions under the new tariff law was whether mineral waters were liable to duty. The collector of the port of New York decided that they were dutiable, but this has been overruled and the decision made that natural mineral waters could be admitted free, though the glass bottles containing the water were liable to duty.

**COLLEGE ATHLETICS AND COEDUCATION.**—Shortly after President Eliot's recent visit to the West the editor of a St. Paul paper thus criticised the University of Minnesota: "A little of the athletic spirit of the Eastern colleges, which the progressive Western educator is so prone to despise, would be a grand good thing to graft into the curriculum at Minnesota's crack educational institution. A small portion of the time the boys spend in 'spooning' under the trees and along the river banks, and in the classic halls with the university maidens could with great advantage be put in the line of healthful athletics. It might discourage matrimony a bit, but it would bring far greater credit to the institution, and be a deal sight better for both youths and maidens."

**MEDICAL RANK IN THE BRITISH ARMY.**—A discussion has been going on for some time in London between Sir Andrew Clark, representing the British Medical Association, and Mr. Edward Stanhope, war minister, in relation to the ranking and privileges of the medical officers of the army. Mr. Stanhope has finally given directions for the preparation of a Royal Warrant conferring the following privileges upon the officers in question: (1) The following substantive ranks to be granted, such ranks to carry precedence and other advantages (except military command, as laid down in present regulations) attaching to the rank indicated by the military portion of the title: Surgeon-major-general, surgeon-colonel, brigade surgeon lieutenant-colonel, surgeon lieutenant-colonel, surgeon-major, surgeon-captain, surgeon-lieutenant. (2) Medical officers to be granted sick leave on the same conditions as those which apply to combatant officers.

**STRAIGHT VERSUS SLANTING WRITING.**—According to the *Medical Press* the Supreme Council of Hygiene of Austria has been engaged in discussing the advantages of erect as compared with slanting writing, and the official report of Drs. von Reuss and Lorenz points strongly in favor of the former. They point out that the direction of the written characters has a marked influence on the position of the body. In "straight" writing the scholar faces his work and is "pared the twist of the body and neck, which is always observable in those who write slantwise, and one com-

mon cause of spinal curvature is thus obviated. The erect method is, therefore, expressly recommended for use in schools in preference to the ordinary sloping lines.

**VIOLATION OF PROFESSIONAL SECRECY IN PARIS.**—The Municipal Council of Paris had recently brought under its notice a curious violation of professional secrecy. The administration sold as waste paper several large bundles of medical reports, dating from 1873, containing the official notification of the demise of people whose names, diseases, and concerning whom other details of a private nature were given. The retail dealers in certain quarters bought the waste paper, and used it to wrap up their wares in when disposed of to the public, who had thus ascertained particulars about the immediate ancestors of their neighbors by no means desired by the latter. The Perfect of the Seine, being appealed to, decided that for the future the documents in question should be destroyed and not sold.

**A THERMOMETER IN THE STOMACH.**—Among the numerous "remarkable medical cases" going the rounds of the daily press, is one of a boy who swallowed a thermometer. To him, *Life* gives the following advice: "If this paragraph should reach the notice of George Martin, who swallowed a thermometer, and if the thermometer is still in him, this is to suggest to him not to make too great a sacrifice to recover it. A surgeon regards a thermometer in a boy's stomach very much as a fisherman regards a speckled trout in a dark pool. The surgeon will suggest that a thermometer in the hand is worth two in the stomach, which is true, but not to the point. What is to the point is that a stomach with a thermometer in it, is worth two stomachs that have been slit and won't hold food. Let the surgeons wait outside, George, and be careful not to take your coffee too hot."

**THE BIOCHEMIC SCHOOL OF MEDICINE.**—A new medical sect has arisen in the West, and has already founded a college in the State of Washington, in which medicine is taught according to the biochemic doctrine, which is thus described by one of the lecturers at a recent meeting: "The innumerable cells of the human body are supplied by twelve mineral salts in the blood, which, when their proper proportion is interfered with in any manner, cause diseases of different natures, according to which mineral salt is deficient or in excess of its natural ratio; that is, the disturbance of this ratio puts the human system into a proper condition to absorb the disease germs that are constantly floating in the air. By providing twelve specific medicines by which the proper proportion of mineral salt is restored, health is regained and disease driven out by furnishing direct to the blood the same molecules that a perfect digestion and assimilation would furnish. The doses administered supply to the tissue cells the special salts, the lack of which is the cause of all diseases. Under the advance of biochemistry it has become possible to apply to each kind of tissue its own definite

and peculiar salt, according to the requirements in disease. By the distinctive systems our physicians are guided in the choice of the particular cell-salts required, the immense variety and numerous complications of morbid states offering vast scope for exact medical practice wherewith to build up the great pyramid of scientific medicine of this advanced era."

**WHOLESALE POISONING AT A WEDDING.**—A few weeks ago in the neighborhood of Louisville, Ky., sixty guests assembled at a wedding and of these no fewer than forty were subsequently seized with symptoms of irritant poisoning, the time of onset varying from four to sixteen hours after eating the luncheon provided. At least five of the persons so attacked died. By a process of exclusion the salad was fixed upon as the incriminated article, none of those who escaped having partaken of it. The salad was accordingly examined by Dr. H. M. Goodman. Its composition was said to be chicken, celery, olive oil, mustard, salt and pepper; and some chicken broth was mixed with it. A careful examination failed to detect any metallic poison, nor did it give the tests for tyrotoxicoin, but the residue obtained after extraction by the Stas-Otto method gave certain undoubted ptomaine reactions, and one cubic centimetre of this injected into the leg of a chicken caused death in three-quarters of an hour. There was strong reason to suspect the chicken broth of being the chief cause, for one of the cooks admitted that she had tasted some of the chicken the day before and that she had been subsequently attacked with symptoms very similar to those of the rest of the victims, and she had not tasted any of the other articles that were served at the banquet. The chickens were killed and cooked on a Monday, and were left standing in the water in which they had been boiled till the following day, the wedding being on Wednesday, and the weather at the time being hot. The symptoms began with pain in the abdomen, followed by vomiting and watery diarrhoea, and it is pointed out that the delay in their appearance is consistent with ptomaine poisoning, but not with metallic poisoning.

#### BOSTON AND NEW ENGLAND.

**DEATHS FROM STROKE IN BOSTON.**—As reported to the board of health, the hot weather of the past week was directly responsible for fourteen deaths.

**THE FISKE PRIZE.**—The Trustees of the Fiske Fund have awarded a prize of \$300 to Dr. Robert W. Lovett, of Boston, for an essay on "The Etiology, Pathology and Treatment of Diseases of the Hip Joint."

**HARVARD MEDICAL ALUMNI ASSOCIATION.**—This young, but already active and flourishing Association held its first annual meeting Tuesday, June 23d, at Hotel Vendome, Boston. The meeting was followed by a dinner at which two hundred and fifty members and guests participated. The President, Dr. James R. Chadwick, presided, and speeches were made by

Drs. H. P. Walcott, Geo. B. Shattuck, H. P. Bowditch, R. T. Davis of Fall River, and F. R. Sturgis of New York. A report was read by a committee appointed to visit the Medical School. The meeting and dinner were in every way very successful, and will be more fully reported later.

**BOSTON CITY HOSPITAL CLUB.**—At the annual dinner, held June 9th, seventy-seven members were present. The President, Dr. F. I. Knight, made the opening address and then called upon representative members to respond for the house-officers of their time. Drs. John G. Blake and David W. Cheever, honorary members, spoke for the "medicine" and "surgery" of the hospital. Among other toasts were those to the "Orator of the Massachusetts Medical Society," responded to by Dr. J. B. Brewster; "The Country Doctor," by Dr. J. F. A. Adams; "Some More of the Surgery of the Hospital," by Dr. G. W. Gay; and "The Massachusetts General Hospital," by Dr. R. H. Fitz. About twenty new members were elected.

**MEDICAL EXAMINERS.**—The Governor of Massachusetts has nominated the following to be medical examiners for the counties named: David W. Hodgkins, Brookfield, Worcester County; George N. Munsell, Harwich, Barnstable County; Silas D. Presbrey, Taunton, Bristol County; Francis A. Harris, Boston, Suffolk County; Frank W. Draper, Boston, Suffolk County; George W. Snow, Newburyport, Essex County; Joseph G. Pinkham, Lynn, Essex County; William Holbrook, Palmer, Hampden County; Theodore F. Breck, Springfield, Hampden County; Lyman H. Tuttle, Holyoke, Hampden County; Francis J. Canedy, Shelburne, Franklin County; Charles Sturtevant, Hyde Park, Norfolk County; Charles C. Tower, South Weymouth, Norfolk County; Alexander R. Holmes, Canton, Norfolk County; Joseph W. Winslow, Easthampton, Hampshire County; William P. Small, Great Barrington, Berkshire County, vice Samuel Camp, whose term expired June 19th. The term for which appointments are made is seven years, and as the medical-examiner law was passed fourteen years ago, the number of terms which expire this year is unusually large. With one exception all are re-nominations. The terms of J. Marcus Rice, Worcester, Worcester County; Jerome Dwelly, Fall River, Bristol County, and James B. Brewster, Plymouth, Plymouth County, have also expired, but no nominations have yet been made.

**LACK OF APPROPRIATIONS IN CONNECTICUT.**—Among the institutions for which no appropriation for the next year was made by the recent legislature are the hospitals at New Haven, Hartford and Bridgeport, temporary houses for neglected and abandoned children, and the collection and publication of vital statistics.

**NEW HAMPSHIRE MEDICAL SOCIETY.**—The annual meeting and centennial celebration of the society was held in Concord, June 15th, 16th and 17th.

A large and interesting programme had been prepared, and the meeting was in every way a success. In addition to many interesting papers, entertainments and excursions were provided. The following officers were elected: President, Dr. Moses W. Russell, Concord; Vice-President, Dr. James H. Wheeler, Pittsfield; Treasurer, Dr. Daniel S. Adams, Manchester; Secretary, Dr. G. P. Conn, Concord; Executive Committee, Drs. Charles R. Walker of Concord, George D. Towne of Manchester, and John R. Kimball of Suncook.

## Miscellany.

### THE TETANIFEROUS MAN.

VERNEUIL<sup>1</sup> applies this term to the individual who carries the virus of tetanus around on his person, although unaffected by the disease himself. The author discusses the causes and means of prevention of this affection from a clinical standpoint. If one considers the horse, with its secretions, excretions and surroundings, as all-capable of propagating tetanus, we cannot regard as impossible, infection by the secretions and excretions of man. The tetanic property of equine saliva has been demonstrated. The saliva of a human being may, for the time being, contain tetanus germs, and thus a bite from such an individual may cause tetanus. A case is given illustrating this. The secretions and excretions are only infected by the ingesta, so that the sperm, milk and urine are never infected with the virus.

He says: "I have already admitted, and now I admit more than ever, that a surgeon, who has dressed a tetanoid patient, may communicate the disease to other patients. I also admit that any person whatever, but above all a physician whose hands have been in contact with a horse, not tetanic, but simply tetaniferous, may infect the wounds of his fellow-beings, as in the cases cited. I also admit, finally, that such a man is not only dangerous to those whom he approaches but may even give himself tetanus by auto-inoculation, either by wounding a part of the skin impregnated with the virus, as the plantar and palmar regions, or touching a wound on any part of his body with his impure hands."

Two cases follow, in which he traces the cause to a wound inflicted on the skin, which was previously infected with the tetanic virus. The bacillus of Nicolaïer was found in one of these cases. Three additional cases are given with a very careful analytical study of each.

### THE ANAL REFLEX.

ROSSOLIMO<sup>2</sup> says this reflex consists in a contraction of the anal sphincters in response to a stimulation of the skin and mucous membrane of the anus. It is invariably present in man in health. The branches of the inferior hemorrhoidal, pudendal, and perineal nerves, on which this reflex depends, are connected with the third and fourth roots of the sacral plexus, which spring from nerve cells in the *conus medullaris*. This reflex can be obtained in the dog as well as in

man, and Rossolimo cut the spinal cord across at different levels from above downwards; whenever the lumbar enlargement was cut across at the level of entry of the third sacral nerve, the anal reflex suddenly disappeared, from which it follows that the cells of the spinal cord which are connected with this reflex are situated in the third quarter of the lumbar enlargement, reckoning from above downwards. In another series of experiments the lumbar enlargement was exposed, and the sacral roots were cut one at a time. By this means it was proved that the anal reflex depended upon the integrity of the third and fourth sacral roots. This reflex, therefore, has its seat in the cord lower than any other reflexes. To obtain the anal reflex the patient may be either standing, the operator separating the glutei, or lying on his side with the legs drawn up. The skin and mucous membrane of the anus may be stimulated by stroking with a pin, a feather, a piece of paper, or some suitable object. The reflex is shown by a contraction of the sphincter ani externus, and if it is very strong there is a drawing in of the whole anus, and even sometimes a contraction of the glutei. In women the testing of this reflex may be conveniently combined with a gynecological examination. The author has examined this reflex in a great many conditions, and he comes to the following conclusion: It is increased in some cases of neurasthenia, in cases of myelitis high up in the cord, and in conditions in which there is a general exaltation of sensations. It is lost in multiple neuritis affecting the sacral plexus, in some cases of tabes, and in myelitis of the lower part of the cord, and in these cases there is generally also anaesthesia of the rectum, anus, and urethra. It remains normal in functional derangements of the bladder, the rectum, and the sexual apparatus.

### SECONDARY SEXUAL CHARACTERS.

PROF. CHARLES STEWART recently delivered a course of lectures before the Royal College of Surgeons,<sup>1</sup> choosing for his subject "Secondary Sexual Character," a term which he defined as comprising those features by which we are enabled to distinguish the male from the female, quite irrespective of the essential organs of reproduction, and which are not concerned either in the nourishment or in the protection of the young.

Where a difference of size is found to exist between the male and the female it is noticed in all plants, in which there are secondary sexual characters, that the female is the larger of the two. The same difference is found in the nematodes, in the rotifers, and, with few exceptions, in the crustaceans. Among the insects very much the same thing exists. In the mammals it is found that, without any exception, where a difference exists, the male is the larger. In the reptiles also the male is the larger. In the amphibia, and nearly all fishes, the female is the larger. Where there is a difference of color, in almost every instance, both in plants and animals, the more conspicuous and brilliant color is presented in the males. In plants the brilliant colors attract the insects, which aid in their fertilization. Thus, in the case of plants, by attracting the insect which is necessary to convey the pollen to the female, color operates to some extent in bringing about that which is effected in animals by sexual

<sup>1</sup> *Lancet*, Feb. 2, 1890. <sup>2</sup> *Gazette des Epiphyseux de med.*

<sup>4</sup> *Neurologie des Centralblatt*, May 1, 1891.

<sup>5</sup> *Lancet*, April 4, 1890.

selection; and it is a fact that in both plants and animals it is the male as a rule which is found to be most conspicuous in color. As regards the sense organs, it is the male in almost every case that shows excessive development of these. The antennae of insects, the eyes, the hairs, are almost invariably more developed in the male. In certain fish, and many other vertebrates, a marked difference in size characterizes the sexes. The more pronounced and outstanding characters are commonly found to be possessed by the male, so that he is able to defend the female and the young, or to fight with his rivals for her favors.

The lecturer then considered the question whether the possession of a certain structure by the male is to be looked upon as having been acquired by him or lost by the female. It has been shown by Poulton that in the case of the antennae of insects there was evidence that in many instances the female had lost the large size and complex form of that sense organ by a process of degradation, and from having altogether different habits of life from the male. In the case of horns, Austin and others hold that originally both male and female possessed the organs, and that the females have lost them, from trusting to the protection of the male, in whom the horns are more developed.

As regards the origin of sex, the illustrations went to prove that so far as our observation at the present time goes, most forms in their primitive state were hermaphrodite to start with. A large number of forms can be shown to be so, and all distinguishing characteristics of the two sexes are probably the result of the advantages accruing from the "division of labor," the female being modified to bear the bulky ova and the male the less bulky, but equally important, fertilizing element. So that there seems to be an advantage in the "division of labor" as regards sex.

In cases high up in the mammalia it has been shown by statistics, that when a race or a nation has been in any way depressed below the normal level, by war or by famine, a rise in the percentage of male births at once occurs. That looks as if there were some direct influence upon the individuals determining the sex of their offspring; and there are cases in which the male functions appear when there is less nutritive vigor, and the female when this vigor has attained its maximum in the same animal.

### PRESCRIPTIONS.

**GLYCERO-ALCOHOLATES.** — Petit<sup>1</sup> recommends the following solvent for many active drugs:

R Glycerin . . . . .	333 parts.
Distilled water . . . . .	147 parts.
Alcohol . . . . .	ad 1,000 parts. M.

This mixture should have the same specific gravity as water, therefore, one cubic centimeter should weigh one gramme. The advantages of this solvent are: that fifty drops weigh exactly one gramme, it keeps indefinitely, evaporation is slow, and it dissolves readily a large variety of substances.

**A GARGLE FOR FOETID BREATH.** — The following has been extensively quoted:

R Saccharin	}	. . . . . 3 i.
Sodium bicarbonate		
Acid salicylic		
Alcohol . . . . .		3 iv.
Oil, menth. p.p. . . . .		gtss. xxx. M.

Sig. Teaspoonful in a wine glass of water, and use several times a day.

**A READY WAY OF DEMONSTRATING THE PRESENCE OF ARSENIC IN WALL-PAPER.** — Put a small piece of the paper into strong ammonia water. If arsenic be present a bluish color will be developed. Since copper gives a similar reaction, as a further test moisten a crystal of nitrate of silver with a drop of the fluid. If the color be due to arsenic, a yellowish deposit will be formed on the crystal.

**PILOCARPINE IN OEDEMA OF THE GLOTTIS.** — Dr. Suarez de Mendoza<sup>2</sup> describes a case in which he was called in to see a young man attacked by serious oedema of the glottis causing suffocative dyspnoea. He suggested that pilocarpine, which he had already found successful in two similar cases, should be tried. Three hypodermic injections were given at intervals of twenty minutes, the total amount of pilocarpine administered being twenty-five milligrammes. Marked relief followed the first injection, and in a quarter of an hour after the third the patient was breathing easily and quietly, and was entirely out of danger. In eight days he was quite well.

**HEADACHE FROM EYE-STRAIN.** — Hare<sup>4</sup> quotes the following from De Schweinitz:

R Tinct. nucis vomice . . . . . 3 iij. M.  
Tinct. cannabis indicae . . . . . 3 iij. M.  
Sig. Fifteen drops in water two or three times a day.

### A PASTE FOR PHOTOGRAPHS:<sup>5</sup>

R Arrow root . . . . .	10 parts.
Water . . . . .	100 parts.
Gelatine . . . . .	1 part.
Alcohol . . . . .	10 parts.
Phenol . . . . .	q. s. M.

Mix the arrow root with a small quantity of water and boil four or five minutes. Soak the gelatine in the 100 parts of water, and mix with the arrow root. When cold add the alcohol and a few drops of phenol.

**STRYCHNINE FOR CHRONIC ALCOHOLISM.** — Ergolski<sup>6</sup> describes ten cases of chronic alcoholism, in which he obtained remarkably good results by subcutaneous injections of nitrate of strychnine, in doses of from one-sixtieth to one-twentieth of a grain. After about a dozen injections the craving for brandy entirely disappeared.

Hyde Park	10,493	2	0	—	—	—	—	—
Pembury	10,158	—	—	—	—	—	—	—

Deaths reported 2,675; under five years of age 1,092; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 455, acute lung diseases 551, consumption 328, diarrhoeal diseases 125, diphtheria and croup 101, typhoid fever 74, scarlet fever 57, measles 42, cerebro-spinal meningitis 22, whooping-cough 17, erysipelas nine, malarial fever eight.

From scarlet fever New York 34, Brooklyn 12, Chicago 6, Philadelphia 4, Boston 1. From measles New York 24, Brooklyn 6, Chicago 5, Milwaukee 3, Philadelphia, Nashville, Springfield and Gloucester 1 each. From cerebro-spinal meningitis Chicago 15, Brooklyn 5, New York 2, Milwaukee and Fall River 1 each. From whooping-cough New York 6, Milwaukee 4, Chicago and Brooklyn 2 each, Baltimore, Washington and Nashville 1 each. From erysipelas New York 14, Brooklyn 2, Boston, Washington and Salem 1 each. From malarial fever New York 1, Baltimore 2, Philadelphia and Brooklyn 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,388,411, for the week ending May 30th, the death-rate was 30.9. Deaths reported 5,568; acute diseases of the respiratory organs (London) 591, whooping-cough 110, measles 94, diarrhoea 42, diphtheria 38, fever 23, scarlet fever 20, small-pox (London) one.

The death-rates ranged from 16.5 in Norwich to 45.9 in Salford, Birmingham 38.1, Bradford 34.6, Hull 30.0, Leeds 29.7, Leicester 28.2, Liverpool 26.7, London 28.9, Manchester 14.1, Nottingham 26.0, Sheffield 23.7, Sunderland 21.6, Wolverhampton 27.7.

In Edinburgh 19.1, Glasgow 23.0, Dublin 18.8.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 13, 1891, TO JUNE 19, 1891.

Lieutenant Colonel JAMES C. McKEE, surgeon, having been found incapacitated for active service on account of disability on duty to the extent, as by direction of the President, retired from office on the above date, under the provisions of section 1501, R. S. For U. S. O. 1-57, A. G. O., June 16, 1891.

Leave of absence for one month, to take effect on or about the 15th proximo, granted Captain RICHARD D. TAYLOR, assistant surgeon, For U. S. O. 65, Department of the Missouri, June 15, 1891.

By direction of the Acting Secretary of War, leave of absence for two months, on surgeon's certificate of disability, with permission to leave the Department of Texas, and authority to enter the Army and Navy General Hospital, Hot Springs, Ark., for treatment therein for a period of one month, is granted Lieutenant-Colonel JOSEPH C. BAILY, assistant medical purveyor. For U. S. O. 134, Washington, June 12, 1891.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 20, 1891.

RUTH, M. L., surgeon. Detached from U. S. S. "Newark," and granted leave of absence for six months with permission to leave the United States.

BRIGHT, GEORGE A., surgeon. Ordered to the U. S. S. "Newark."

PIGOTT, M. R., assistant surgeon. Ordered to the U. S. S. "Independence."

WELLS, HOWARD, surgeon. Detached from Naval Hospital, Chelsea, and wait orders.

STEELE, J. M., passed assistant surgeon. Ordered to Naval Hospital, Chelsea, Mass.

## THE AMERICAN SOCIETY OF MICROSCOPISTS.

This association will hold its fourteenth annual meeting in Washington, D. C., August 10th, and continue in session five days. We invite and urge upon all persons, professional or amateur, interested in microscopy and not already on the rolls, to send in their applications for membership to the Secretary, Dr. W. H. Seaman, No. 1427 Eleventh Street, Washington, D. C. The application should be accompanied by \$3.00, which is the initiation fee and one year's dues. Any further information concerning the society, or the approaching meeting, may be obtained on addressing Frank L. James, President, Box 568, St. Louis, Mo.

## DEATHS.

LORENZO S. FOX, M.D., M.M.S.S., of Lowell, died June 23d, aged fifty-one. Dr. Fox graduated from the Harvard Medical School in 1865, and immediately enlisted as assistant surgeon of the Twenty-sixth Massachusetts Regiment. He was president of the Middlesex North District Medical Society in 1876, surgeon of the Lowell Hospital, and member of the British Medical Association.

JOSEPH W. ALSON, M.D., of Middletown, Conn., died June 24th, aged fifty-two. He served six terms in the State Senate, and was elected Lieutenant-Governor of Connecticut last autumn, but on account of the political disturbance in the State, had not taken his seat.

HORACE RICHARDSON, M.D., M.M.S.S., died in Boston, June 18th, aged sixty-one. Dr. Richardson graduated from Harvard College in 1852, and from the Medical School in 1855. He had spent many years abroad, and had only just returned at the time of his death.

AMERSE PRATT, M.D., died in Chester, Conn., June 18th. He graduated from Yale in 1837, and during the war served as surgeon in the Twenty-second Connecticut Regiment.

SIR FREDERICK GARDNER HEWETT, BART., F.R.C.S., died in London, June 20th. He was one of Her Majesty's sergeant-surgeons, and was also surgeon in ordinary to the Prince of Wales.

JAMES K. LANE, F.R.C.S., a once prominent surgeon of London, died June 6th, aged sixty-six.

## BOOKS AND PAMPHLETS RECEIVED.

Syphilis of the Lung. By W. T. Councilman, M.D. Reprint. 1891.

Leprosy and Vaccination. By William Tebb. London: E. W. Allen. 1891.

Away with Koch's Lymph! By Nicholas Scum, M.D., Ph.D. Reprint. 1891.

Mind is Matter, or the Substance of the Soul. By William Henstreet. New York: Fowler & Wells Company.

Observations on the Amoeba Coli in Dysentery and Abscess of the Liver. By George Dock, M.D. Reprint. 1891.

Wiring of the Vertebrae as a Means of Immobilization in Fracture and Pott's Disease. By B. E. Hadra, M.D. Reprint. 1891.

Further Studies in Malarial Disease. The Parasites and the Forms of Disease as Found in Texas. By George Dock, M.D. Reprint. 1891.

The Diagnosis of Traumatic Lesions in the Cerebro-Spinal Axis, and the Detection of Malingering Referred to this Centre. By E. A. Watson, M.D. Reprint. 1891.

# INDEX TO VOLUME CXXV.

**Abbot, S. L.** Two cases of post-partum hemorrhage with special features, 623, 630.

**Abbott, A. C.** Immunity and infection, 637.

**Abbott, S. W.** The distribution of diphtheria in Massachusetts, 561, 588.

**Abrams, A.** Parenchymatous aspiration, 46.

**Adamkiewicz** treatment of cancer, 601.

**Africa.** European colonization of Central Africa, Moore, W., 149.

**Agnier, D. H.** Present status of brain surgery, based on the practice of Philadelphia surgeons, 356.

**Alanus.** The results of vegetarian diet, 506.

**Albumin.** How much shall be included in the term "albumin"? Smith, A. H., 44.

**Albuminuria** in persons apparently healthy, 18.

**Alcohol.** Dipomania, Baker, W. H., 296; on the rôle of alcoholism in the etiology of general paralysis, 277.

**Allen, H.** The tonsil in health and disease, 445.

**Allopecia.** A therapeutic note on alopecia areata, Bulkley, L. D., 527.

**Althaus, J.** The neuritic character of influenza, 638.

**Ammonia.** A case of ammonia poisoning, with unusual features, DeCosta, J. M., 677.

**Anaemia.** Pathology of pernicious anaemia, Griffith, J. P. C., and Burr, C. W., 442.

**Anæsthesia.** The discussion on anæsthetics at Glasgow, 90; a new method of producing local anæsthesia, Wieselender, 208.

**Anatomy.** Recent progress in anatomy, Dwight, T., 545.

**Aneurism.** Compression in the treatment of aneurism, with the description of a new appliance, Beach, H. H., A., 100, 112; incision of a false iliac aneurism, Bradford, E. H., 593, 601; aneurism of the aorta, Fitz, K. H., 603.

**Animals.** Animal diseases, Dundas, E. L., 550.

**Anus Medicus MDCCXCXI.** 713.

**Anthony, F. W.** A case of pulmonary edema secondary to nephritis, complicating pregnancy, 468.

**Appendicitis.** Discussion, 36, 63, 84; the pathological anatomy of the appendix cæci, with special reference to acute and chronic appendicitis, Whitney, W. F., 113; appendicitis: a year's experience in private practice, Elliot, F. W., 135; two cases of appendicitis, one associated with uterine fibroid, the other with pregnancy, Mixer, S. J., 697, 702.

**Apostoli.** The Apostoli method of treatment, its technique, Burrage, W. L., 561, 572.

**Army.** The condition and prospects of the library of the surgeon-general's office and its index catalogue, Billings, J. S., 344.

**Arsenic.** Evidence as to the injuriousness of arsenic as a domestic poison, Crafts, J. M., 71.

**Aseptic** and antiseptic details in operative surgery, Warren, J. C., 37.

**Aspiration.** Parenchymatous aspiration, Abrams, A., 46.

**Atkinson, I. E.** Bradycardia in acute articular rheumatism, 414.

**Atrophy** in joint diseases, Brackett, E. G., 469, 617; a study of atrophies in children, Park, R., 470.

**Ayer, J. B.** Mental disturbances of influenza, 294, 296.

**Bacilli.** Shortening of Bioret's method for finding tubercular bacilli in the sputum, Kronig, 263; the increasing importance of bacteriology in its relation to internal pathology, 447.

**Baker, L. W.** The semi-private care of epileptics, 651, 653.

**Baker, W. H.** Small sub-serous fibroids of uterus the occasion of great intolerance of the bladder, 189, 196; dipomania, 296; cancer of the cervix uteri, results in its treatment by high amputation, 601.

**Baldy, J. M.** Insanity following gynecological operations, 657.

**Barton, W. R.** Acute prostatitis and prostatic abscess, 275; the treatment of gonorrhœa, 276.

**Barlow.** The treatment of Pott's disease, with special reference to the stage, 496.

**Baths.** Permanent public baths for the poor, 278.

**Beach, H. H. A.** Compression in the treatment of aneurism, with the description of a new appliance, 100, 112.

**Beckings.** Medical school libraries, Warren, C., 280.

**Becker, J. A.** Bogus Medical College in Washington, 283.

**Beely, F.** Pathological anatomy of lateral curvature of the spine, 500.

**Berry, J. J.** The internal use of germicides, 443.

**Bertrich.** Morbidity in different occupations, 610.

**Bibliography.** Adams, W., electricity, its application in medicine and surgery, 146; annales des sciences psychiques, 197; Army; index

catalogue of the library of the surgeon-general's office, volume XII, 286; Army: the condition and prospects of the library of the surgeon-general's office and its index catalogue, Billings, J. S., 344; Assay, institut de chirurgie, 174; Beard, G. M., sexual neurasthenia (nervous exhaustion), its hygiene, causes, symptoms and treatment, with a chapter on diet for the nervous, 66; Beard, G. M., on the medical and surgical uses of electricity, 578; Bigelow, H. R., plain talks on electricity and batteries, with therapeutic index, 41; Brown, F. H. the medical register for New England, 503; Binet, A., the psychic life of micro-organisms, 253; Canfield, W. R., practical notes on urinary analysis, 501; Cappel, J., the intra-cranial circulation and its relation to the physiology of the brain, 116; Champneys, F. H., on painful menstruation, the Harehart lectures, 1890, 284; Chapman, H. C., memoir of Joseph Leidy, M.D., LL.D., 631; Charcot, J. M., œuvres complètes, 174; Clouston, T. S., the neuroses of development, 577; Delfield, F., studies in pathological anatomy, 500; Foster, F. P., an illustrated encyclopædic medical dictionary, 529; Foster, M., a text-book of physiology, 474; Gatchell, C., pocket medical dictionary for the use of students of medicine, 501; Gibbs, H., practical pathology and morbid histology, 501; Gowers, W. R., a manual and atlas of medical ophthalmoscopy, 684; Talliburn, W. D., a text-book of chemical physiology and pathology, 533; Hare, H. A., essentials of physiology, 631; Hare, H. A., fever, its pathology and treatment by antipyretics, 63; Herschel, G., indigestion, a manual of the diagnosis and modern treatment of the different varieties of dyspepsia, 681; Hewitt, G., on severe vomiting during pregnancy, 653; Hippocrates: the genuine works of Hippocrates, 146; Kingsbury, G. L., the practice of hygienic suggestion, 632; Knapp, P. C., the pathology, diagnosis and treatment of intracranial growths, 631; Lang, A., text-book of comparative anatomy, 712; Leftman, H., progressive exercises in practical chemistry, 501; Leonard, C. H., the vest-pocket anatomist, 276; Liebig, G. A., practical electricity in medicine and surgery, 41; Loring, E. G., text-book of ophthalmoscopy, 712; Massachusetts State Board of Health, annual report, 1890, 477; Miller, W. E., the micro-organisms of the mouth, the local and general diseases which are caused by them, 253; Muter, J., a short manual of analytical chemistry, 633; Nettleship, E., diseases of the eye, 684; Newth and Owen, post-mortems, what to look for and how to make them, 501; Noxia, R. C., syllabus of the obstetrical lectures in the medical department of the University of Pennsylvania, 530; Ochrowsicz, J., mental suggestion, 577; Parker, W. T., records of the Association of Acting Assistant Surgeons of the United States Army, 632; Parvin, T., the science and art of obstetrics, 553; physician's visiting list, 681; Potter, G. W., ministering women, the story of the royal national pension fund for nurses, 601; Regnier, L. R., hypnotisme et croyances anciennes, 263; Ribot, T., the diseases of personality, 632; Seiple, E. A., essentials of pathology and morbid anatomy, 520; Shakespeare, E. O., report on cholera in Europe and India, 635; Shattuck, F. C., auscultation and percussion, 276; Shaw, J. C., essentials of nervous diseases and insanity, 632; Shoemaker, J. V., heredity, health and personal beauty, 146; Sisley, R., epidemic influenza, notes on its origin and method of spread, 630; Sorinsky, T. L., medical symbolism in connection with historical studies in the arts of healing and hygiene, 631; Soury, J., les fonctions du cerveau, 197; Starr, L., diseases of the digestive organs in infancy and childhood, 500; Thompson, E. S., influenza or epidemic catarrhal fever, 630; Tyson, J., a guide to the practical examination of the urine, 501; Uffelman, J., manual of the domestic hygiene of the child, 385; Whipple, F. H., a guide to the clinical examination of the urine, 530; Winckel, F., a text-book of obstetrics, including the pathology and therapeutics of the puerperal state, 655; Withrals, R. A., the medical student's manual of chemistry, 553.

**Bigelow, H. R.** Plain talks on medical electricity and batteries, 479.

**Billings, J. S.** Ideals of medical education, 1; the condition and prospects of the library of the surgeon-general's office and its index catalogue, 344.

**Bibliography.** Asher, W. C., 392; Atwater, H. H., 232; Baillargone, J. M., 420; Beckings, J. A., 280; Bell, J. C., 120; Bevan, R., 720; Brune, T. B., 560; Campbell, H. F., 720; Clark, S. T., 720; Cochran, J. J., 508; Collins, R. P., 492; Cogswell, W., 286; Damainville, L., 692; Day, A., 422; Donaldson, F., 641; Dubois, A., 260; Dunham, G. D., 612; Dupac, H., 180; Dyer, H., 336; Emerson, W., 124; Garret, C. C., 68; G. R., 124; Gouley, R. T., 200; Griffith, J. P. C., 66; Hahn, G., 443; Hatch, H., 284; Hirschler, L., 610; Hitchcock, J. G. S., 232; Husted, N. C., 581; Ives, L., 612; Jay, J. C., 660;

- Johnston, C., 424; Jones, T. W., 646; Jones, W. W., 72; Keefe, J. P., 284; Kulob, J. A., 284; Krumpholtz, G., 132; Loring, G. B., 308; Lyman, G. H., 232, 256, 257, 334; Lytle, H. G., 640; Macdonnell, R. L., 180; Mills, A. M., 208; Minter, J., 726; Murphy, P. J., 392; Osborne, E. A., 480; Page, P. W., 392; Paine, O. S., 560; Pardee, D., 241; Peck, W. F., 601; Pincus, F., 308; Polak, J. S., 480; Pratt, T., 250; Pugh, F. F., 590; Robinson, S., 492; Rogers, H., 440; Rothman, E. C., von, 622; Russell, E., 480; Ruth, M. L., 664; Sawyer, E., 692; Seanzon von Lichtenfels, F. W., 72; Schultz, S. S., 392; Sheppard, C. E., 134; Skinner, A., 132; Smith, C. D., 640; Smith, S. S., 134; South, H. P., 134; Spang, C., 408; Spangstedt, C., 692; Speer, J. R., 234; Spotswood, W. W. A., 284; Stone, W. H., 124; Storer, D. H., 203, 209; Sutherland, J. A., 200; Sutton, H. G., 48; Tobey, J. E., 152; Van Wyeck, W. H., 559; Vinciguerra, A. E., Z., 72; Von Marxow, W. P., 590; Watt, C., 436; Wedd, C., 486; Weiss, W., 124; Wells, O. P., 124; West, M. C., 436.
- Bladder.** A contribution to the treatment of rupture of the bladder, Cabot, A. T., 396.
- Blake, C. J.** Otagia, 165, 173.
- Blake, G. S.** Some gynecological cases at the Boston City Hospital, 622, 629.
- Blindness.** A law for the prevention of blindness, 178.
- Bodies.** The condition of bodies long buried, Holmes, W. H., 79.
- Bowdoyer, P. H.** Compulsory notification of infectious diseases, 333.
- Bosworth, P.** Various forms of disease of the ethmoid cells, 445.
- Bowditch, V. Y.** The condition of the streets in Boston, 252.
- Bowen, J. T.** Report on pathology, 191; the question of a mixed infection from syphilis and tuberculosis, 166; the pathology of cutaneous tuberculosis, 716, 726.
- Brackett, E. G.** Atrophy in joint disease, 469, 617; paraplegia in Pott's disease, 476.
- Bradford, E. H.** Metatarsal neuralgia, or "Morton's affection" of the foot, 52, 63; the comparative value of present modes of treatment of the spine, 495; the treatment of congenital dislocation of the hip, 408; means of recording rotation in lateral curvature, 500; modifications in the treatment of lateral curvature, 500; incision of a fatty filar spurium, 595, 601; bullet-wound of the skull, 594, 602; trephining for epilepsy, 602.
- Bradford, E. H., and Brackett, E. G.** Recent progress in orthopedic surgery, 679, 700.
- Bradford, E. H., and Smith, H. L.** Penetrating pistol-shot wounds of the skull, 600.
- Bradycardia in acute articular rheumatism**, Atkinson, I. E., 414.
- Bra n.** Present status of brain surgery, based on the practice of Philadelphia surgeons, Fawcett, D. H., 536.
- Breast.** The benign manner of growth of the mammae, McGillivray, T. J., 115; the recurrence of cancer of the breast, Dennis, F. S., 379; a case of diffuse fibroma with a tendency to intra-canalicular growth of both breasts, Porter, C. B., 381.
- Breves, F. M.** Torus, with description of an automatic forceps for fetal version, 541, 552.
- Bright's Disease.** The prodromal and early symptoms of Bright's disease, Wilmington, C. F., 16, 263; on the diseases of the kidney popularly called Bright's disease, DeHafeld, F., 412; hygienic treatment of Bright's disease, 412.
- Brodthurst, B. E.** Gonorrheal rheumatism and its treatment, primary and secondary, 469.
- Bryce, P. H.** The present position of the milk-supply problem from the public health standpoint, and some practical methods for securing safe public supplies, 551.
- Bucklin, C. A.** A nasal saw, 558.
- Buckley, L. D.** A therapeutic note on alopecia areata, 527.
- Bullard, W. S.** Spastic paralysis in children, 196.
- Bullets.** The cause of the erratic course of some bullets, Hall, J. S., 690.
- Bum.** Gonorrhea in the female, 565.
- Burrage, W. L.** The Aposth method of treatment, its technique, 565, 572.
- Burrell, H. L.** A case of gastrostomy, 710.
- Burrell, H. L., and Cushing, H. W.** Recent progress in surgery, 12, 373, 406.
- Cabot, A. T.** Fibro-myoma of the uterus removed by hysterectomy, 162; a contribution to the treatment of rupture of the bladder, 396; three cases of compound fracture of the patella, in which the bones were wired with good effect, 537, 552; internal strangulation, 682.
- Cesarean surgery.** The present and improving status of Cesarean surgery, Harris, R. E., 67.
- Cancer.** Incubation of cancer, 206; researches on the parasitic nature and infectiousness of cancer, 379; the recurrence of cancer of the breast, Dennis, F. S., 379; Adamkiewicz treatment of cancer, 691.
- Car sanitation.** Daniels, W. W., 551.
- Centrifugal force in clinical diagnosis**, Litten, 121.
- Channing, W.** Physical education, 1.
- Chaycan.** Transformation of the small-pox virus, 583.
- Children.** The clinical course and the principles of treatment of tetanic ankle disease in childhood, Sender, C. L., 69; treatment of constipation in children by abdominal massage, Karulitzky, 121; hemorrhages in the newborn, Townsend, C. W., 218, 221; the treatment of knee and hip-joint disease in young infants, Wilmington, C. F., 239; entomological researches upon the saliva of children, outbreaks from measles, 203; address before the American Pediatric society, 415; a study of atrophies in children, Park, R., 170; on the etiology of epilepsy, with special reference to the connection between epilepsy and epilepsy, Wilton, G. L., and Carson, C. F., 184, 191; spastic paralysis in children, Bullard, W. S., 196; the cause and prevention of infant mortality, McDonald, D., 51.
- Children's present models**, 563.
- Chloron.** The gentle treatment of Bright's disease, 531.
- Chloroform.** A study of chloroform, 70; contributions to the study of chloroform, with special reference to its connection with heart disease and the respiratory system, Wilson, S. G., and others, 469.
- Chloroform.** R. M. E. Chloroform in food, with absence of great toxic effects, in connection with the liver, 469.
- Circulatory System.** Cerebral hemorrhage, 17; heart-strain, Elliott, W. L., 6; tachycardia, Frauentz, B.; compression in the treatment of aneurism, with the description of a new appliance, Elliott, W. L., A. A., 132; bradycardia in acute articular rheumatism, Atkinson, I. E., 414; the relations between arterial disease and visceral changes, Peabody, G. L., 438, 458, 481; on changes in the red blood-corpuscles in the pernicious anemia of Texas cattle fever, Smith, T., 445; sequel to a case of slow pulse, Prentiss, D. W., 472; aneurism of the right popliteal artery, Dennis, F. S., 174; pericarditis with large hemorrhagic effusion in a patient with Graves's disease, repeated puncture, double dry pleurisy, recovery, Shattuck, F. C., 491, 494; incision of a false iliac aneurism, Bradford, E. H., 595; aneurism of the aorta, Fitz, R. H., 603; recent progress in thoracic disease, Sears, G. C., 624; unsuspected heart disease, Vickery, H. F., 639, 706.
- Clark, J. P.** Sarcena of the nose, with report of a case, 239, 251.
- Cleveland.** Laporotomy in Trendelenburg's posture, with exhibition of a new operating table, 629.
- Climate.** American climates and their physical effects, Remondino, P. C., 550.
- Cocaine.** A kind of oedema sometimes following the injection of cocaine, Newell, O. K., 553.
- Coe, H. C.** Accidental hemorrhage occurring during the first stage of labor at term, 574.
- Coggin, D.** Some points in ocular therapeutics, 663.
- Cohen, J. S.** The symptoms and pathological changes in the upper air passages in influenza, 446.
- Collapse.** A few hints on the treatment of collapse, Mumford, J. G., 11.
- Columbian Exposition.** The Medical Bureau of the Columbian Exposition, 267.
- Common sense in medicine**, Gordon, S. C., 233, 261.
- Congress.** An Inter-Continental American Medical Congress, 19.
- Conner, P. S.** The late manifestations of syphilis, 354.
- Conthard, G. E.** Pleuritic effusions, 259.
- Conzuman, W. T.** Syphilis of the lung, 22.
- Cowles, E.** Neurasthenia and its mental symptoms, the Shattuck lecture for 1891, 49, 73, 97, 125, 153, 181, 209.
- Crafts, J. M.** Evidence as to the injuriousness of arsenic as a medicine, 527.
- Criminal.** The study of the criminal, 578.
- Croton water-supply**, 301.
- Carrier, A. F.** A study relative to the functions of the reproductive apparatus in American and Indian women, 606.
- Cashin, E. W.** Pathological questions, 708.
- Cutaneous System.** A case of annual shedding of the skin, Frank, J., and Sanford, W. C., 151; report on dermatology, Bowen, J. T., 194; address before the American Dermatological Association, Townsend, C. W., 310; clinical aspects and etiological relations of cutaneous tuberculosis, White, J. C., 509, 526; the pathology of cutaneous tuberculosis, Bowen, J. T., 509, 526; the therapeutics of cutaneous tuberculosis, Fox, G. H., 521, 526; report of a case of uni-lateral pyoderma multiforme, with a note on the etiology of the disease, history of a case showing modification and amelioration of symptoms with large doses of arsenic, Sherwell, S., 525; notes of a visit to the leprosy hospital of San Remo, Italy, Dubring, L. A., 527; skin griffing, Morrow, P. A., 527; a therapeutic note on alopecia areata, Dubring, L. A., 527; exanthema, Dubring, L. A., 527; ring-worm in an institution for boys, Dubring, L. A., 527; molluscum contagiosum, Graham, J. E., 528; note relative to pemphigus vegetans, Hyde, J. N., 529; a case of ichthyosis vegetans, Stelwagon, H. N., 529; a case of lichen ruber, Grindon, M., 529; tuberculosis of the skin, 531.

## Addresses.

### IDEALS OF MEDICAL EDUCATION.<sup>1</sup>

BY JOHN S. BILLINGS, M.D.,  
*Surgeon in the United States Army.*

(Continued from Vol. CXXIV, No. 26, page 623.)

HAVING thus roughly sketched what is wanted in the way of medical education by different classes of students—the article for which there is a market, let us next consider briefly what an university may wisely attempt to provide in this direction. Some suggestions on this point may perhaps be obtained from an examination of the condition of affairs as regards medical education in the University of Oxford.

The Corporation of Oxford has a little more than half the number of inhabitants possessed by the city of New Haven, and its relations to London are, in many respects, similar to those of New Haven with the cities of New York and Boston. For a number of years it has been urged by some physicians in England, that the University of Oxford with her great resources, has not been doing as much for medical education as she should have done, and that it is her duty to establish and maintain a completely organized medical school of the usual pattern, using the small local hospital and dispensary facilities for the clinical side of the work.

On the other hand, other physicians, of whom my friend Sir Henry Acland may be taken as the representative, maintain that it is much better that Oxford should use her resources in giving a broad foundation of literary and scientific culture, including, for those who propose to study medicine, the means of special instruction in general biology—and in comparative and human anatomy, physiology and pathology—and that the men thus prepared should go to the great Hospital Medical Schools of London to obtain their clinical training, after which, they may return and pass their final examinations and obtain the coveted degree of Doctor of Medicine from the University.

There is no doubt that this can be done, and that a great part of the scientific foundation of a complete medical training can be furnished by a well-equipped university, with little or no reference to clinical instruction at the same time and place. This, for example, is the course followed by many of the students in the Medical Department of the University of Virginia, and it seems to me that there is also no doubt that the men who go through such a course of training, followed by clinical training in a great city, will have a better course of instruction, a wider experience, and a better chance of seeing and appreciating the methods of great clinical teachers, than would those who obtained their clinical as well as their scientific training, in the small town, or than those who obtain all their instruction in a school devoted exclusively to medical studies. Upon this last point I need not dwell, for Dr. Welch, in his address before you in 1888, has clearly pointed out the advantages of giving to a medical school an university atmosphere, and of making the union of the school and the university close and intimate. It should be noted, however, that the more true this is, the more it is the duty of an university to maintain such a school, because educational work which cannot be, or is not, done so well

elsewhere, has superior claims upon university aid. The chief thing which can be said in favor of the attempt to attract a large number of medical students of average qualifications to an institution having the means to give the higher education are, first, that it brings in more money, and, second, that it enables those professors who desire advanced workers, to select these from a somewhat wider field.

It must be confessed that nearly all our great American universities are unwilling to apply their funds to the creation and maintenance of a well-equipped medical department. They are willing to have such a department no doubt, but they want the money for establishing and maintaining it to be provided in addition to money which has been, or is to be, provided for the general purposes of the university. The ideal university culture of the present day appears to be designed to fit a man to take pleasure in his own thoughts and musings and in mental exercise in languages, literature, the higher mathematics, and the problems of physics and natural history. Incidentally his knowledge of these things may not only give him pleasure, but enable him to help others, but the studies are not to be pursued on account of any practical utility which they possess, but for the love of learning and pure science, that is, for personal gratification of a particular kind. Those who hold these views are apt to consider medicine as a technological matter, which should be left altogether to special schools, because, being practically useful in a commercial sense, the means of teaching it are sure to be provided through commercial interests, just as they are sure to be provided for the teaching of practical engineering. This is far from the old university idea as embodied in the three faculties and four nations of the University of Paris. So far as the interests of the public are concerned, it is only the possession and control of a large amount and variety of clinical material, or of unusually qualified clinical teachers, which makes it the positive duty to use it, or them, for purposes of medical instruction in order to train ordinary general practitioners of medicine. There is no present deficiency in the number of such practitioners, and we certainly have plenty of schools for producing them, so that there is no fear of failure in the supply.

But in medicine as in every other profession, art or trade, the supply of the best is never too great, and the demand for something better than that which already exists never ceases.

What then does an university, or its medical school, need in order that it may be able to supply the demand for this higher medical education? First, competent teachers. Second, suitable buildings, collections, books and apparatus. Third, clinical material. To secure and retain these things requires money, and brains to use it. First, as to the competent teachers. There are many teachers available, but the number of these who have shown that they are competent for, and suited to positions in a medical school which is to supply the best and something better, is limited—much more so than one who has not tried to find them would suppose, and these few are not seeking engagements. How many anatomists, or physiologists, or pathologists, of the first class, thoroughly trained, authorities in their special fields, capable of increasing knowledge, and with the peculiar gift of ability to teach—do you suppose there are in this country? It is a liberal estimate to say that a

<sup>1</sup> Address delivered before the Medical Faculty of Yale College, June 23, 1891.

dozen of each have thus far given evidence that they exist. And the great clinical teachers in medicine and surgery, the men who are up to the times in matters of diagnosis, pathology and therapeutics, and who are also successful teachers both by the spoken and written word—how many such have we—and especially how many such have we who are not fixed and established, so that they may be induced to go to a school which needs them? Such men are either men of genius, and even this boasted nineteenth century has produced them rarely, or they are men of talent made the most of by unflagging industry with special opportunities, and these are also rare. Yet these are the men whom a great university should seek to obtain and retain for her faculties. To do this, and to get the best work from such men, is by no means a mere matter of salary, although sufficient salaries must be paid. We have also to consider the buildings, collections, books and apparatus required, and this is largely a question of money. How much money? What would be the cost of establishing and maintaining a first-class medical school in this country at the present time? Let us suppose that one hundred and fifty students are to be provided for—that the course of instruction for those coming with a good high-school education is to occupy four years, and for those coming with the degree of Bachelor of Arts, and having done at least one year's work in a chemical laboratory and one year's work in a biological laboratory, the course shall occupy three years, that the last year's studies shall be almost exclusively clinical, and that provision is to be made for advanced post-graduate work.

We shall want, then, practical anatomy rooms for fifty students, a physiological laboratory, a pathological laboratory, a pharmacological laboratory, a laboratory of hygiene, and the means of clinical teaching, a library and a museum. The days have long gone by when one or two amphitheatres or lecture-rooms and a small museum were all the outfit required for medical teaching. The little amphitheatre of the University of Bologna was sufficient for almost every purpose of medical teaching, as that was carried on three hundred years ago, but now the lecture-room is the smallest part of the outfit required. In his evidence before the Royal Commission, Professor Lankester stated that to establish such a medical school at Oxford as he thought desirable, about \$225,000 would be required for buildings, in addition to those already existing, and that about \$100,000 a year would be required for running expenses. Professor Billroth estimates that about \$100,000 would be required for buildings for the medical department of a university, exclusive of the buildings for clinical teaching, which he thinks would cost about as much more; and that the annual expense would be about \$105,000. He says that these estimates are based on an average standard of efficiency—not the highest—and concludes by saying: "Let us hope that a rich man may some day give three millions of dollars to found a school to be devoted to medicine and natural science."

Perhaps the figures may seem high to you. Yet building is cheaper and salaries lower in England and in Germany than with us, if only first-class work and first-class men are accepted. To build and equip a laboratory which shall give work-room for seventy-five men, will cost here between \$75,000 and \$100,000. At least four such laboratories are needed by

the ideal medical department, besides a building for general lectures, library, etc., which would cost about \$50,000.

It is, of course, possible to consolidate all these into a single three- or four-story building, and thus save money, especially in cost of ground, but the results are not so good. I am not speaking now of temporary, makeshift buildings, but of permanent structures, which though plain should not be hideous, and should be thoroughly well built. Where land is abundant and not too dear, it is usually better to construct these laboratories one at a time, and endeavor to secure for each a proper endowment and equipment. The average expenses of each laboratory may be put at \$15,000 per annum. In other words, it requires about \$400,000 to build, equip and endow a physiological, pathological or hygienic laboratory such as is suited to the needs of a first-class university in this country. By paring down in various directions, this sum can be reduced to \$300,000, but not lower without seriously impairing the efficiency of the plan. And in all this I have said nothing of the cost of the means for clinical instruction, which should be borne, in part at least, by the school, for the simple reason that only by doing this can the school have that control of hospital appointments which is so necessary for its proper work.

Of course, every professor who is skilled and energetic, and who is imbued with the true university spirit, has innumerable wants and suggestions which require money to supply and carry out. He wants the new books and journals relating to his specialty, specimens, apparatus, models and illustrations; and if he is at the head of one of the laboratories which I have named, the sum of \$15,000 per annum will be required to pay him and his assistants, and to provide for their needs. All this means that the educating of physicians on this plan will cost the medical department between four and five thousand dollars for each graduate. It will receive from them eight hundred to one thousand dollars each, and the balance must be made up from subscriptions, appropriations or endowments. Practically, endowment is the only resource.

The student himself has to give four or five years' time and labor, and four or five thousand dollars, to obtain his medical education. For some, this expenditure of time and money will be an excellent investment; for others, not, even if they have enough of both to spare for this purpose. After all, the most that the university can do is to afford opportunities for learning, and a certain kind and amount of stimulus to mental work. The professor may declare that he will teach certain branches; but there are some sent to him for instruction who are not teachable, and the only thing he can do is to return them as little damaged as possible.

The number of men for whom it is specially desirable to provide laboratory and other special facilities for original work in physiology, pathology, pharmacology and hygiene is limited. There are not a great number of men who have the desire and the qualifications necessary for this sort of work, and the number of positions in which they can find remunerative employment in devoting themselves to such investigations, is still more limited.

The laboratory facilities in Germany are, as a whole, at present in excess of the number of properly qualified men who can be found to make use of them, although a few are overcrowded.

Advanced work and original investigations cannot, as a rule, be made by undergraduates, if for no other reason than that of lack of time.

Is it advisable that the same medical school shall undertake to furnish such different courses as to provide for all wants — to offer to meet the minimum requirements for the degree of Doctor of Medicine, as well as the wants of those who demand more advanced and detailed instruction? The answer to this depends largely on the location of the school, and on the means which it can command, especially as regards facilities for hospital and clinical instruction. In any case, its diploma of Doctor of Medicine should have an uniform value, and if it does undertake the double function, the higher education must be largely post-graduate work. It must also be, to a great extent, a voluntary matter on the part of both schools and students.

As indicated at the beginning, this address is not intended to criticise existing medical institutions, or to give specific advice to any college or university. I have simply tried to formulate roughly what seems to be the present ideal of a course of medical education in the minds of many physicians, and then to show what the carrying out of this ideal involves to the schools and to the students.

I believe in ideals, that is, in their beauty and in their utility when they do not dominate a man so as to make him a visionary, or a dangerous crank or fanatic; but one ideal is often more or less incompatible with another, and all of them must be held subject to the possibilities afforded by surrounding circumstances. But we must not be too sceptical about these possibilities. And we are all directly interested in this matter, every one of us. Every one of this audience will probably see the time when the knowledge and skill of the physician called in to advise in the calamity which has fallen on him or his wife or child will seem to him of vast importance.

Sometimes he can select his physician, often he cannot, but must rely on the first one who can be found. Hence these discussions about medical education, although chiefly carried on by physicians, because they are most familiar with the difficulties of the subject, should be considered by those who are not physicians quite as much as by those who are, or intend to be. It is a dangerous business, however, for a doctor to discuss other doctors in public. He can make more trouble for himself in less time in this way than by almost any other method that I know of. Nevertheless, it is my duty to tell you that there is little probability that the ideal facilities for higher medical education, either here or elsewhere, will be furnished by the doctors themselves. There are several reasons for this, but one is sufficient, and that is, they have not got the money, which I have shown you is necessary to provide and maintain these facilities. Hence, if these ideals are to be realized, the means must be furnished by those who are not members of the medical profession, and it seems to me that this is what will be done.

What is the best way for a university, a real university, to begin this line of work? In most cases I should say by establishing one department at a time on a proper basis. Which departments should be the first to be thus established? Just here is where many of the doctors will begin to differ.

I should say that the first of these departments to be provided for are two which will form the main

links in the university bond between the medical and other departments, — covering two branches of knowledge which every university graduate should study somewhat, namely, biology and hygiene. For the clergyman, the teacher, the journalist, and the sociologist, systematic instruction in these two branches is as desirable as it is for the physician — for the lawyer it will be useful — only the philologist would I excuse entirely from these departments.

Of course, in specifying that they are to teach, and to teach undergraduates, I do not mean that teaching is to be their sole function. This is not the modern idea of a scientific department of a true university. It is to increase knowledge as well, to provide for the needs of special investigators and seekers who have obtained their elementary training elsewhere.

Let the plans for such a department be well thought out, the expenses carefully estimated, and then bring the matter to the attention of those who have the means to realize this ideal, and sooner or later it certainly will be realized. I have elsewhere ventured to express my sympathy for two classes of men who have in all ages and in all countries received much disapprobation from philosophers, essayists and reformers, namely, rich men and those who want to be rich.

So far as the wealthy are concerned, there seem to be a good many of them in these latter days who use their stored force to endow universities and professorships, to build libraries and laboratories, and to such let us give due praise and honor.

They may not be scientific men, but they make scientific men possible. The unscientific mind has been defined as one which is willing to accept and give opinions without subjecting them to rigid tests. "This is the kind of mind which most of us share with our neighbors. It is because we give and accept opinions without subjecting them to rigid tests" that the sermons of clergymen, the advice of lawyers, and the prescriptions of physicians have a market value. The unscientific public has its uses,<sup>3</sup> and one of its characteristics is a liking for ideals, some of which it occasionally helps to realize. I can only hope that whenever an American university approves the ideal which I have roughly sketched, this public will see that the means are provided for carrying it out. It may be objected by some that it would be better to help to raise the average standard by endowing chairs in the medical schools in large cities, than to provide special facilities for the use of a limited number. It is quite true that all medical schools should be endowed; and this is coming, for voluntary associations of physicians, who are not a wealthy class, cannot afford to compete with endowed schools when State laws shall come to enforce a high standard of requirements. Nevertheless, we need universities properly so called, as well as colleges and higher schools, and we need university men in the medical profession as well as elsewhere.

I have no fears as to the creation of a medical aristocracy by giving facilities for higher education to those who have the means to avail themselves of them. It is quite true that only a fraction of those who have the means will use these facilities properly, and that there will be a number who have not the means who would make good use of such facilities if they could get them; but these last will not be helped by the

<sup>3</sup> Scientific Men and their Duties, by J. S. Billings, Washington, 1886.

total absence of such facilities for anybody. Let us try to give the best minds a chance to obtain the best training, let us try to discover these best minds wherever they may be, and if their owners have not the means to avail themselves of training, let us try to furnish the means. But to do this, one of the first and most essential steps is to provide somewhere the teachers, and the buildings and apparatus, necessary for giving such instruction, and where is a better place to do this than in connection with an university? or, if you please, in connection with this University?

### PHYSICAL EDUCATION.<sup>1</sup>

BY WALTER CHANNING, M.D.

I SUPPOSE there is no one who is more conscious that some terrible mistake has been made in our system of civilization than the physician engaged in the treatment of the insane.

Whenever he looks at the noble men and women, and the children of other noble men and women, who are hopeless mental wrecks, never to be any better, and destined to descend into a state, essentially animal in character, he is startled and shocked, and feels almost impelled to say: "Here is the real fall of man, here is man become beast!"

To me the cause of this degeneracy never became fully apparent, until my attention was directed toward "physical education." Then the scales fell from my eyes, and I found the explanation wide and deep to be sure, but still a fairly satisfactory explanation, resting on a perfectly rational basis.

In the first place, I found the doctrine of evolution was of great assistance in solving the problem. This showed me man, beginning as the slightest possible sentient unit, slowly and by almost imperceptible steps, developing from a creature with a simple uniform structure, to one with a complex, multiple structure. First, with a nervous system like that of very low animals, then by slow stages, after thousands of years, reaching the highest point of development, so far.

I also saw further, which impressed me with the nearness of man to the animals, that each human being before birth possesses a fundamental likeness to different animal forms.

Here I was brought face to face with the fact that man is physically essentially animal and equally dependent for further growth on physical laws. Obey these laws, and growth would continue; disobey them and it would be interfered with, and finally stopped.

And what has happened? Is it not true that the body has been treated like a watch or a special piece of mechanism, to use an illustration of Fiske, created for a special purpose and not like a flower, a plastic organism of slow growth, slowly adapting itself to its surroundings?

Nature works slowly and thinks little of centuries, but is inexorable in the end. Is it not true that the nervous mechanism, the mental side of man, has been subjected to a process of forcing, perhaps for centuries, which is only just beginning to be felt?

The body, the plastic organism, has been neglected during all these centuries, and at last, as an incident, in what I believe to be a pushing or reaching upward to a still higher state of existence, a temporary break-

down, a lack of harmony with, a want of adjustment to, the environment, asserts itself.

Just here it is well to remember the immense importance of heredity. An English writer<sup>2</sup> has well said: "The stability or instability of a person's highest nervous arrangements, depends primarily and chiefly on inheritance. Every man is the outcome and product of his ancestry . . . the small amount of new character that circumstances can produce in any individual in comparison with the character transmitted to him by his ancestry, may be gathered from the length of time that circumstances can act on him, in comparison with the aggregate length of time during which the long line of his ancestry have been subject to modification by circumstances."

We are suffering now from the effects of mistakes made by our ancestors for unknown centuries. Physical instability of certain kinds has resulted. Correct these mistakes along properly indicated lines, and in the end we shall see healthy growth, where now we see threatened decay.

What is the brain? An immense double organ of nervous centres made up of millions of cells, receiving primarily their whole knowledge of existence through the muscular structure, and retaining this knowledge, not only for its own use, but for that of succeeding generations. Systems of education, forms of government, social institutions, are the outgrowth of temporary needs, and can be both established and destroyed arbitrarily, they are not a vital, organic part of life. But every movement of a muscle, every tremor of a nerve fibre, every shock of a brain cell, has a fixed, definite, organic value, which has a bearing on the health and growth of the human organism.

We cannot afford to forget or lose sight of the fact that through muscular movement and effort man has struggled to his present preëminence. But we also cannot afford to forget that this preëminence has been reached by a sacrifice, through ignorance of a certain amount of the vitality and strength of the organism itself.

Our steps must be retraced or turned in a new direction, until the external impression, and the internal expression are mutually adjustable and convertible.

Finally, it is to the cumulative and transmitted effects of physical education on future generations that we are to look, in applying methods now. The more nearly adapted naturally to the organism, the more in keeping with the laws of its growth and development, the more valuable will be the final results.

HONORS TO MEDICAL MEN.—When they want to honor medical men in the monarchies of Europe, they present them with different orders, generally of some bird. We notice, for instance, that the practising physician and health counsellor Schmidtborn, of Saarbrücken has been given the red eagle order of the fourth class. But imagine the feelings of a doctor on receiving such honors as this: "His Majesty, the King, has been most graciously pleased to give his most august permission that the staff surgeon, Dr. Brunnhoff, shall wear the Mecklenburg grand ducal house order of the Vandal crown, the Medschidje order of the third class of the Turkish grand-signor, and the commander cross of the royal Portuguese military order of the conception of our beloved lady of Villa Viçosa."

PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

BY HAROLD C. ERNST, M.D.,  
*Instructor in Bacteriology at the Harvard Medical School.*

I SHALL endeavor to give a short review of the cases that I have had under treatment with Koch's material during the last four months, without in any way feeling that the conclusions that may be reached this evening are final.

For the opportunity to make the observations here recorded, and the cases upon which they are based, I am indebted to the staff of the Massachusetts General Hospital, of the Boston City Hospital, and of the Children's Hospital. And for the records, both of the cases and the microscopic examinations, my most hearty thanks are due to the various gentlemen who have assisted me all the time that the work has been going on. To attempt to name every one who has helped, would make too long a catalogue of names; and I hope that these gentlemen, even though not specifically mentioned, will feel that any success that may be given to this preliminary report is in large part due to their efforts.

The cases that have been treated or examined at least once, number fifty-two, and include all varieties of tuberculosis, from the simple and uncomplicated form of pulmonary disease, to extensive affections of the skin and joints. As they will be published, they will be divided into: (1) Pulmonary, either uncomplicated or with minor affections of the other parts of the body (this class numbering twelve); (2) surgical, —including, for convenience sake, the two cases of lupus that have been under my care, as well as all other forms of this class of tuberculosis (these number twenty-two); (3) those cases that have been treated in the first place for diagnosis (which number eight); (4) the cases that have been under observation for too short a time to make the record of value as regards the point we are trying to establish. This last class also includes the records of three cases that were refused treatment for various reasons; for it would seem to be a matter of interest to show why this treatment should be refused, as well as why it should be given.

In every case the observations have been made as carefully as possible, and the records are as full as circumstances would allow. There is not absolute uniformity in this respect, for the reason that it was not possible to obtain force enough for the complete daily carrying out of all of the observations. At the Massachusetts Hospital I had the assistance of Dr. A. K. Stone, for a part of the time; and at the City Hospital, Drs. Arnold and Fay did as much as their other duties would allow in helping on the work. Throughout the whole time, Dr. Henry Jackson has looked after the microscopic work with the most untiring energy and faithfulness.

Except where especially stated, no other treatment has been employed whilst the injections have been going on. Where it was possible, fresh sputum-cups were employed; new ones being supplied twice a day, and the old ones (of paper) being burnt after the specimens were obtained for the microscope. In all cases of microscopic observation, absolutely new and unused

cover-glasses and slides were used; and all the microscopic work was done at my laboratory at the Harvard Medical School. In cases of any doubt as to the appearances, the specimens were submitted to me, but the record will show who was responsible for the actual examination.

The object has been throughout, to obtain as accurate an observation of what the material will do as could be reached with the cases at command.

Before going any further in the account of what has been accomplished, it would seem to be as well now as any time to speak of the possible dangers that may arise from the employment of tuberculin, the fear of which has taken such a hold upon many minds. And first, as coming from the greatest pathologist of the age, the utterances of Virchow. Dr. Jackson has been good enough to collate this author's published statements for me, and they are given as follows, including also the remarks of one or two others: (1) Israel<sup>2</sup> inoculated a rabbit in the eye with pus and a bit of tissue removed by operation from a case that had been treated with tuberculin for five weeks.

Bacilli were found in the tissue under the microscope, and tubercle developed in the eye; thus showing that the treatment does not destroy the bacilli. (2) Virchow<sup>3</sup> gives the result of twenty-one autopsies on cases subjected to the treatment up to January 1, 1891, as well as six afterwards, and also speaks of a number of similar cases examined by his assistants, of which he had seen the principal organs. Of the twenty-one cases, sixteen were phthisis in the narrow sense; that is to say, the principal lesion was in the lung. In all sixteen cases, ulcerative processes of greater or less extent were found; in fact, these cases belonged to true consumption (*Schwinducht*.) "I give no details of the cases, only general remarks." As in external parts the chief manifestations of the injections are represented by acute inflammation with marked redness and swelling, so I find the same thing in the internal organs."

Virchow demonstrated one specimen as a perfect example, — the brain and membranes from a case of acute tubercular meningitis. In the lungs were found old tubercular processes, which furnished the starting-point for the acute processes. There had been four injections, the last sixteen hours before death; in all, there was used .002 of the material. There was an enormous (*kolossale*) hyperæmia of the pia, as well as of the brain substance itself, "such as I do not remember ever to have seen before." Virchow himself examined the tubercles, and did not find any change suggestive of a retrograde process; the tubercles presented the characteristics usually observed.

Similar acute hyperæmias and swellings were observed in other internal organs; several times hemorrhagic infiltration of the walls of the cavities, and even fresh hemorrhages in the cavities. These processes were not simple hyperæmic swelling; but it was easily demonstrated that inflammatory processes, with actual tissue growth, had taken place. The lymph glands were swollen to an unusual degree. Such swellings as these may at times assume a dangerous character, as in ulcerations about the throat. In the cases of ulcerative phthisis, the larger number showed fresh processes of considerable size, especially in the lungs; usually also, pleurisy at the same time, simple or tuberculous, and not seldom double.

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1891.

<sup>2</sup> Berl. Klin. Woch., January 5, 1891.

<sup>3</sup> Berl. Klin. Woch., January 12, 1891.

The changes in the lungs may be divided into two classes: (1) Cheesy pneumonia, or, anatomically, cheesy hepatization. "In these cases, doubt may be felt whether the cheesy hepatization had anything to do with the injection. I myself should throw out any such connection, except that a few of these cases have a special significance. Example: A lung was demonstrated with very numerous cheesy masses all through the lower lobes. The lung substance between the cheesy masses was infiltrated with blood and leucocytes. The specimen came from a man thirty-three years of age; there had been six injections, the last four weeks before death. The injections were stopped on account of continuous fever and infiltration of both lower lobes, which did not clear up. The infiltration came on after the injections were begun, as at first there was only induration at one apex. Several cases were noted, but none so marked as this. (2) Pneumonia, similar to catarrhal. Virchow remarked that he could not precisely define how these cases of pneumonia differed from the usual catarrhal pneumonia, but the chief difference was that the material pressed out from the alveoli was watery and cloudy, suggesting rather a phlegmonous condition.

"As to the other observations, a condition was found which must be tested by a number of clinical cases carefully studied; and that is the occurrence of fresh tubercles. I do not speak of small tubercles whose age we cannot estimate, but of submiliary nodules, of whose age we can speak with certainty. I can say that I have observed in internal organs and in those that I consider the most reliable for the observation of these fresh forms, that is, serous membranes, the eruption of absolutely fresh submiliary tubercle under conditions which rendered it hardly likely that they were of any considerable age." There was no evidence presented of any degeneration of fresh tubercle; and Virchow throughout his paper, lays especial emphasis upon the fact that small and submiliary tubercles — those not already degenerated — presented no change secondary to the injections with tuberculin. He goes on to say: "As to the origin of these new eruptions, the question must for the time be set aside. However, I would remark, that if we consider that all tubercles are produced by bacilli, we should pay especial attention to tubercles situated at a point remote from the original focus of the disease, as for instance the pleura." A small tuberculous patch on the epicardium was shown, situated at a distance from the affected part of the lung, where no contact was possible." There was here no possibility of infection except by a metastatic process. Why should not we think of a metastatic process, and allow the expression of the suspicion as to whether the bacilli had not been rendered mobile, whether they had not been spread through the body in the path of intension (*Auf dem Wege der Intension*)? . . . The bacilli are not destroyed by the treatment (as declared by Koch and demonstrated by Virchow), so that the possibility cannot be denied that when a softening occurs in any place, which renders the detritus (*Zerfallsproducte*) more fluid, or at least more movable, these bodies (the bacilli) may also be swept along, and produce new patches in other places. . . . Another question arises when, under injection, a whole lower lobe becomes filled with patches of cheesy pneumonia, whether the cheesy material in the upper lobe has not been loosened; very likely aspirated into the

lungs; and so produced a form of 'feeding pneumonia' (*Schluck-pneumonie*)."

Virchow seemed to be especially impressed with the absence of all change in submiliary tubercles, and often in those of a larger size. He also warned against the use of the injections in people who were so far reduced, that they were unable to remove by cough and expectoration any cheesy and loosened masses.

All of the results that are spoken of by Virchow, are those that would suggest themselves to one who was familiar with the subject, and indicate the caution with which the material should be used. The necessity for this had impressed itself upon my mind before I had seen much of its action or many cases in Berlin; and so much so, that from the first, I have pursued the plan of using smaller doses, and not in any case attempting to reach those of the excessive size that are sometimes quoted. The choice seems to lie before us of securing a violent reaction and possible benefit in cases that are strong enough to bear it, or attempting to attain the same end, of benefit to the patients, with smaller doses, and these spread over a longer time. Pursuing this latter course, I have had no deaths that are in the least fairly attributed to the treatment; one of the two that are recorded being due to an intercurrent attack of pleurisy, and the other distinctly a death from exhaustion, the case being desperate from the first. On the other hand, although I have no case of cure to report (and any such case reported at present must be received with scepticism), the percentages of cases that seem more or less better after the treatment (whether simply after it or on account of it, is still an open question), are about the same as those reported from Germany.

The next point that has aroused alarm, is the statement coming from Liebmann, of Trieste, that he had found bacilli of tuberculosis in the blood of many of his patients after treatment with tuberculin, and not at other times or in other cases. Of course, if this were true, it would be a most crushing piece of evidence against the safety of the method and the wisdom of those who employed it. There is fortunately an article\* that is suggestive, to say the least, upon this point. I give, as nearly as possible, a literal translation of it. It is a report of a meeting of the Berlin Medical Society:

"Herr Kossel reports the result of the examination of a preparation of blood that was sent from Herr Liebmann (in Trieste) to Professor Ehrlich. The preparation contains, besides blood-corpuscles, bacilli of tuberculosis in such great numbers, that, if one should draw from these a conclusion as to the number circulating in the blood, it would be a question of millions. It may, therefore, be difficult to see why a report of severe illness was not made in regard to the patient of Herr Liebmann. Furthermore, masses of three and more bacilli are found in the preparation. Such formation occurs in masses of dead material and bacilli, when they stagnate for a long time; in the circulating blood a like occurrence is improbable. Finally, it seems as if the preparation was dirty, and the bacilli were always in proximity to such masses of dirt. As one is not justified in doubting the statements of Herr Liebmann upon a single preparation, he was asked to send more, which request he complied with. In seven other specimens, also, it was

\* Deut. Med. Woch., March 19, 1891.

conspicuous that the bacilli lay mostly near the edge of the cover-glass, and it was conjectured that these did not originate in the blood. The proof of this was manifest, since in one place, the remains of sputum containing bacilli were found. Also, in several other preparations places were found later, which were absolutely unmistakable as the remains of secretion. The statement was confirmed by Herren P. Guttman, Ehrlich and Kitasato. Probably through an unfortunate accident, cover-glasses were used which had served before for sputum examinations, and which were not sufficiently cleaned. Herr Liebmann, to whom this report was communicated, insisted that he had found bacilli in new preparations which were made upon absolutely clean cover-glasses. In the City Hospital Moabit, nine cases further were examined with precise following of the methods of Herr Liebmann, with uniformly negative results."

Comment upon this communication is hardly necessary, the more especially as no other observer has reported any results at all to confirm Liebmann's assertions.

Similar examinations were, however, made of the blood of sixteen of the cases I have had under observation, and, after a very varying length of treatment, with absolutely negative results. All the examinations were made the day after an injection and in the following cases: No. 1, seven weeks after the beginning of treatment; No. 2, six weeks after; No. 3, the same; No. 4, the same; No. 8, five weeks after; No. 8, four weeks after; No. 12, three examinations, one week, four weeks and five weeks after; No. 22, four weeks after; No. 32, four weeks after; No. 25, seven weeks after; No. 30, five weeks after; No. 49, one week after; a case of Dr. Beach's, seven weeks after, and one other.

The results of such examinations seems to make it fairly certain that such an accident as that under consideration, has at any rate, never yet been actually traced.

This exceedingly brief consideration of the dangers of the method brings us at once to the consideration of the cases I have to report. I wish to state as distinctly as possible at the very outset, that the conclusions presented are but preliminary, as they must be at the best; and that I should feel at perfect liberty, cause being given, to change my opinion of any individual case tomorrow. I can only give the results as based upon the condition of the patient at the last time that he was seen.

The classification of the cases is also imperfect. I give them as cases treated with tuberculin; and the diagnosis of tuberculosis I do not consider settled in any of them in which the bacilli of that disease have not been demonstrated. This, of course, may at times bring up a conflict of opinion from the clinical point of view; but one of the lessons that we must learn from the sort of investigation of which this is a part, is a closer and more exact diagnosis, as based upon modern methods.

(To be continued.)

A TELEGRAM from Simla contains an announcement which points to a distinct advance in the bacteriology of leprosy, due to the researches of the members of the Leprosy Commission. It is to the effect that Drs. Rake and Buckmaster have succeeded in cultivating the leprosy bacillus in serum.

## TWO CASES OF SYPHILIS.<sup>1</sup>

BY W. F. TEMPLE, M.D.

KATE M., age twenty-four, single. Family history good. Of her previous history could learn nothing with the exception of diseases of childhood. At the time of first consultation complained of dysmenorrhœa, from which she had never suffered before last period.

On March 11, 1885, was summoned to her house, when the following symptoms were noted: Considerable prostration, pain in back, headache, difficulty of deglutition. These she had been suffering from for three or four days previously. On examination the tongue was found to be coated, and the whole pharynx red and swollen; externally the tonsils were noticed as much enlarged. Heart and lungs normal. Temperature 101°, pulse 90.

March 18th. For past week has been growing steadily worse. Tonsils very much swollen. Two cold-sores, size of little finger-nail, have been noticed for the past two days; one on upper lip to right of median line, the other on the lower lip to the left of median line. To-day, for the first time, left sub-maxillary gland enlarged. Cold-sores more carefully examined. The one on the upper lip had the appearance of an ordinary herpes labialis. That on the lower lip had more of the characteristics of a small tumor; the base was not indurated; edges thin and irregular; the size that of a silver five-cent-piece; covered with a thin pus. Just anterior and to the left of soft patch was a sharply defined ulcer, size of little finger-nail. Probe passed a quarter of an inch and came down upon denuded bone. (Iodoform and cleanliness.)

March 20th. Much the same condition as at time of last visit. Anæmia increasing; sub-maxillary gland more swollen (tonies). Temperature ranged from 99° to 101°, and pulse from 90 to 95, during past ten days.

March 23d. Crust over both cold-sores. Ulcer of same character as that recorded on the 18th, noticed to right and anterior to soft palate, though not so deep. Throat very much swollen; mucous membrane dark red in color; tonsils projecting markedly. Left sub-maxillary gland much enlarged, tense, reddened, indistinct fluctuation. (Cleanliness and iodoform.)

March 26th. Condition unchanged with exception of sub-maxillary gland, which has become more swollen; distinct fluctuation. Etherized and gland opened, discharging about one-half teaspoonful of thick pus. (Poulticed.)

March 27th. Very uncomfortable, restless night. Throat less red; ulcers on hard palate healing. Gland opened yesterday discharged somewhat freely during night.

April 1st. Throat better; complains of headache; cold-sores almost well; more appetite. (Tonics.)

April 4th. Throat still improving. Temperature and pulse normal. Continued to improve for four or five days, but on April 12th the combination recorded is languor; muscular pain in back, arms, legs and thighs; cold-sore on lower lip healed, the one on upper lip still present, indurated; throat still red.

April 15th. Decidedly worse. Temperature 102°, pulse 110. Complaints of severe headache.

April 18th. Occipital glands still enlarged. Few scattered papules over entire body, most numerous

<sup>1</sup> Read before the Boston Society for Medical Observation, March, 1891.

over back. General condition unimproved. Corrosive sublimate, one-thirtieth of a grain every four hours.

April 21st. Still much headache. Febrile condition continues. Dr. Post saw the case in consultation, and advised pushing treatment.

April 23d. Saw case for last time to-day. Family dissatisfied. From the physician who superseded me, learned that the case under treatment gradually improved.

My diagnosis was chaneroids of lips and throat. Bubo of sub-maxillary gland and primary syphilis.

The ethical questions arising from a case of syphilis may be very perplexing, in this case the mother forming an opinion, the family eagerly supporting her, the patient wholly unconscious of her dreadful malady; their conclusion is formed at once as soon as the disease is made known to them, for the young lady is engaged, the only possible way for them to look at the case is that the disease is a gift of a lover's kiss, they reject the possible chance of its being due to an entirely different source, and should you accuse or allow him to be accused by the family unjustly, nothing could atone for such a step. The plan was, when sure of the diagnosis, to have quietly told the patient, to have questioned the lover, and helped them keep their secret. My successor at once announced the source of the trouble and its probable cause to the family, thus gaining their esteem and possibly doing one man a great wrong. Review of our cases is always a useful study; in this, my course was such as to cause no regret.

From a medical point of view the case is instructive from the fact that the true initial lesion occurred on the same base as the chaneroid, also that the eruption, which was papular, was not of the character which usually ushers in the syphilides; both of these conditions though occurring, are by no means common. The primary lesion showing itself in the location that it did in this case, made the diagnosis more cautious and difficult to make.

One point in the treatment: we are not justified, according to my way of thinking, in beginning specific treatment until secondary symptoms appear: this we were taught, and mature consideration leads me to give perfect assent to the teaching. Keep the chancre clean and defer other than tonic treatment until perfectly sure of the diagnosis.

CASE II. M. E., age thirty-five, grass widow. Family history good. Previous history good. Has been sick for four or five weeks with what was called slow fever. At time of this visit, November 23, 1885, the following record was made: Morning and evening temperature the same, 100°, pulse 94; dull aching pain in back and thighs.

November 25th. Both knees and ankles red, swollen and painful. (Five grains of salicylate of soda every hour.) Temperature 102°, pulse 96.

November 26th. Pain not so severe; otherwise record same as yesterday.

December 1st. Joints not quite so painful; right eye painful; photophobia; slight conjunctivitis; pain also in supra-orbital and infra-orbital regions. A prominent oculist saw the case with me, and advised pushing the salicylate of soda (ten grains every hour), solution of atropia (1-100), and dark room.

December 3d. Very little change; pain in joints still continues; eye symptoms somewhat relieved. (Five grains of salicylate every hour.)

December 11th. For past week has been at times more comfortable, though pain has still continued in joints. Last night very restless; severe pain, lancinating in character, in back, thighs, and back of head; urine normal. Salicylate discontinued. Treatment expectant.

December 14th. Throat somewhat sore; other symptoms not much improved. Delirious during the night; has strange fancies this morning, though is not violent as she is said to have been during the night. Eye in much the same condition as a week ago, with exception of conjunctiva, which is much inflamed. Atropia has been continued. Pupil large, evenly dilated. Few small papules (rose-colored) noticed on face, hands and back. (One thirty-second of a grain of corrosive sublimate every two hours, ten grains of iodide of potassium t. i. d.)

December 15th. Much worse; has been wholly without reason for the past twenty-four hours. Requires to be constantly watched to keep her in bed; has strange fancies; hears voices; continual muttering.

December 18th. Papules increasing in number and size. Condition of eye somewhat improved. Has been delirious for most of the time for past three days, occasionally wildly so, oftener of a dull, muttering character, at times seems to know when spoken to, but imagines that she is away from home.

December 20th. Somewhat improved; severe headache at nights noticed when conscious; eye much improved; delirious most of the time, but not wildly so. Dr. George H. Tilden saw the case in consultation, and by his adviceunctions of mercurial ointment were given. Iodide of potassium rapidly pushed up to one and a half drachms t. i. d.

December 24th. Very much improved; free from headache for past twelve hours; complains of sense of fullness in ear; tinnitus aurium; right drum dull red color (no bulging); course of vessels could be plainly seen; gums red and tender. (Chlorate of potash mouth wash, omitted mercury.)

December 29th. Continues to improve. Has been about the house for past two days. Eye very much improved; can stand the light; has been comparatively free from headache.

I would say, in closing the history of the case, that she was under my observation for three years; that when last seen she had been entirely free from any symptoms for six months, though she fully understood the value of iodide of potassium, and always kept it as a possible need in the house.

Syphilis may simulate almost any disease so perfectly as to mislead the most careful clinical observer.

Dr. Duncan Bulkley, in an article read before the New York State Medical Society, reports observations on four hundred and fifty cases, with the following results: Neuralgia was noted as a special symptom in nineteen cases; sciatica, apparently due to syphilis, in five cases; headache caused by syphilis in twenty cases; in one very striking case dementia was caused by this disease, which yielded very rapidly and perfectly to anti-syphilitic treatment. Rheumatism was recorded as occurring thirty times; bursitis in five cases. There were twenty-three cases of eye lesions due to syphilis, mostly iritis. Epilepsy is once recorded. In twenty-nine cases alopecia formed a striking feature. Six deaths are recorded as due to syphilis.

In our case the symptoms were in the onset such as to justify one in making a diagnosis of acute rheumatism.

During the past few years much attention has been paid to cerebral syphilis; for myself and the happy result in this case, the aid given by Dr. F. B. Greenough is cheerfully acknowledged, as it was the help received from an article of his, published in the *Boston Medical and Surgical Journal*, June 11-18, 1885, that the case was made clear. He reports five cases of cerebral symptoms, with early syphilis. In these five cases headache was a prominent premonitory symptom, and moreover, headache having certain well-marked and definite characteristics, such as a decided tendency to exacerbations towards evening, its severity, and its very quick yielding to the administration of iodide of potash. Dr. Greenough says: "I have seen many cases that I am convinced would have resulted in cerebral trouble had they not been recognized and treated." This would have been the result in the case reported.

The rarity of cerebral symptoms with the early manifestation of syphilis is acknowledged by writers on this subject. In this respect our case is interesting, as well as from the fact that the severe headache with nocturnal exacerbations, together with the marked delirium, antedated the appearance of the eruption; and when the papules began to show themselves, in fact, throughout the course of the disease, they were very few in number, and might have been overlooked as syphilitic, had it not been for the severe cerebral symptoms. In this fact of being the indicator of syphilitic trouble, rather than indicated as of syphilitic origin by the eruption, the case is peculiar.

Dr. Denslow reports, in the *North-western Lancet* for May 1, 1885, four cases of persistent headache in early syphilis, in all of which the phenomena were observed within six months from the appearance of the primary lesion. Of course, the diagnosis is very much easier in those cases where the symptoms of constitutional infection are present, or so shortly afterward that the fact of the patient's having recently had syphilis cannot be ignored. One interesting point in Dr. Denslow's paper was the fact that in one case where treatment had been neglected complete hemiplegia, with aphasia, came on, which freely yielded to anti-syphilitic treatment.

One word only on treatment. The advice of Sturgis is very true. He says, in giving both mercury and iodide of potash, "Watch your patient well, to obviate the occurrence of toxic symptoms, and do not hesitate to use either one or both remedies in sufficient amount to dispel the symptoms, no matter what the requisite dose may be." This is especially true in regard to the use of iodide in those cases with cerebral symptoms, where the small doses fail wholly, when by pushing the dose to sixty, to eighty or one hundred grains, happy results are obtained.

INFLUENZA IN LONDON. — There seems to be a marked decline in the fatality of influenza in London. The deaths directly referred to this disease, which had been 319, 310, and 303 in the preceding three weeks, further declined to 249 during the week ending June 13th. In addition to these 249 deaths, there were 49 cases in which influenza was certified to have occurred in the course of other diseases.

## CLINICAL ASPECTS OF INFLUENZA FROM A COMPARATIVE STANDPOINT.

BY KENELM WINSLOW, M.D.  
Instructor in Materia Medica and Comparative Therapeutics,  
Harvard University, Veterinary Department.

In presenting this brief sketch the writer trusts that he is not trespassing upon the already tried patience of a long-suffering and much-enduring medical profession. The only excuse is the comparative point of view.

A survey of the field as exhibited by the manifestations of *la grippe* in the lower animals, more especially the horse, may throw some side-lights on the general clinical picture of this disease.

Influenza is one of the common disorders to which the horse is subject, perhaps the most frequent, more particularly in the cities. The reason for this great prevalence is that influenza in horses is both enzootic and epizootic.

**Etiology.** — The causation of the malady is as vague and uncertain as it is in man. Moreover, it is still unsettled as to whether the disease is contagious or infectious or both. On the one hand, cases have developed on shipboard where a sufficient time had elapsed to apparently preclude the possibility of contagion; on the other hand, it is a most patent fact that the germs of the affection hang about and infest certain localities, so much so, that when a young animal is introduced into such places, an invasion is well-nigh inevitable. It may be added that inoculation and transfusion of blood from the diseased animal to the healthy have thus far failed in reproducing influenza.

Poorly ventilated and crowded city stables, where the disease has long had a foothold, are the favorite resorts in which horses most readily develop the disorder. This is, indeed, so well recognized that many city dealers have an out-of-town establishment in connection with their business in which they place green horses, that is, young animals brought from the country.

The constitutional disturbances which horses suffer on being transferred from one part of the country to another, and more especially from the vicinity in which they are bred to the city, known as acclimatization, is usually nothing but influenza, that is, where the trouble amounts to anything more than a slight cold. The period of incubation appears to be from five days to a week.

It will, therefore, be seen that influenza in horses differs from that in human kind in being always with us. It is, however, particularly common during spring and autumn, and more often occurs in the unfavorable surroundings alluded to above, rather than in the better hygienic circumstances of well-ventilated quarters and in the purer air of the country.

Young animals are the most frequent sufferers. Whether this is because they are the most susceptible, which seems probable, or because they are then for the first time made liable to the disease, through transportation heretofore noted, cannot be fully determined. But it is generally conceded that the older the animal the less likely is the disease to become contracted, not only because an earlier attack has perhaps secured a certain degree of immunity, but because the more aged become the less susceptible. In general the weak, overfed and overfat are rendered more sensitive to the disease.

Influenza likewise occurs in the lower animals, as

we have said, in the epizootic form, and its severity then is much increased. The earliest authenticated plague of this description took place at the beginning of the fourteenth century, and since then it has made its appearance in widespread and violent outbreaks at irregular intervals.

The last epizootic is fresh in the minds of our readers, when in 1870-72 it extended from Canada southward, and then spreading out, east and west, ravaged the entire country. In some of these epizootics other animals than horses have been attacked, notably dogs, and even poultry have been reported to have suffered.

It is rather curious, in this connection, that epidemics occurring synchronously among human beings have been rarely observed. It is related, nevertheless, that an epizootic in England in 1776 was followed by an epidemic of a like nature among men. Apropos of this consideration, influenza among the lower animals has not been remarkably prevalent during the recent and prevailing scourge of *la grippe* in man.

**Clinical Features.**—There is much resemblance between influenza as seen in human medicine and as observed in the horse, and yet some differences. In the latter animal the attack is often ushered in suddenly by visible rigors, loss of appetite, cough, and mucous discharge from the nostrils and eyes. The severe frontal headache of human beings is probably absent in horses, as symptoms of head trouble manifested by "boring" the head, as rubbing the occiput against the sides of the stall is called, are not observed; neither is the presence of pain in the back noticed in horses, but Prof. C. P. Lyman, of the Harvard Veterinary Hospital, has frequently noted pain in the limbs as among the earlier symptoms. The absence of suffering may be explained from the fact that neuralgic affections are almost unknown in veterinary practice. The temperature (normally  $100^{\circ}$  in the horse) rises to  $102^{\circ}$ ,  $104^{\circ}$ , or even  $106^{\circ}$ ; the pulse (normally 36 to 40 pulsations per minute) becomes 60 to 80, and is weak and easily compressible. The respirations (normally 12 to 18) reach 30 to 40 to the minute. A peculiar feature of the disease is the salmon color taken on by the visible buccal, Schneiderian and conjunctival mucous membranes which is almost pathognomonic.

The disorder is as prostrating in character, and more apt to become complicated than in man. Especially in epizootics do many animals die from exhaustion and "heart-failure." After the first invasion the symptoms usually increase in intensity for two or three days. The discharge from the nostrils and eyes becomes more profuse; the cough increases; the animal is stupid and weak, stands with the head depressed in a listless way, and when moved sways about in an unsteady manner. The throat is often sore; swallowing is difficult, and causes coughing, and the patient regurgitates food and water through the nose; there is considerable thirst, anorexia and constipation.

The period of maximum intensity, following that of invasion, is maintained for about four days, when the fever and other symptoms abate gradually, and convalescence sets in. Great prostration follows a decline of the acute attack, and is often accompanied by oedema of the tissue about the under surface of the belly, the sheath of the penis and the legs.

**Résumé.**—Influenza, then, in the horse, resembles

that affection in man, in that the local symptoms are out of proportion to the great systemic disturbance, or in other words, it is an essential fever with local manifestations. It is, however, enzootic, and in that way differs materially from the affection among human subjects, where a case apparently influenza would be discountenanced as such if it should occur sporadically.

The neuralgic symptoms in the horse, as we have seen, are much less prominent. The duration of an attack is about the same; but the liability of healthy young subjects to dangerous complications is considerably greater than is observed in the same description of human patients.

Although there is a certain immunity established by a prior attack, yet if an animal be worn out and run down, especially during epizootics, there is great likelihood of a recurrence.

Good, strong animals rarely succumb, save by complications.

Predisposition to other affections and permanent after-effects, so often following the human malady, rarely are seen in veterinary medicine. The complications are numerous and dangerous in the horse. Briefly they are: Severe conjunctivitis, often purulent, where it is termed "pink-eye"; acute laryngitis, frequently demanding tracheotomy; swelling, and often suppuration of the sub-maxillary and parotid glands; bronchitis; pneumonia, the most common fatal complication, of an asthenic type; pleuritis; rheumatoid affections, attended with great swelling, difficulty of motion and pain in the joints; digestive disturbances, evinced by constipation, jaundice, colicky pains; and not rarely, diarrhoea, which not infrequently proves irremediable; congestion of the brain; congestion of the laminae of the feet; and not uncommonly endo- and peri-carditis, with its attendant results and fatality.

There are other rarer complications and sequelae, but the preceding are the more common.

**Treatment.**—The one remedy that is generally held in most esteem, and properly so, is quinine, given in doses of from fifteen to thirty grains, in conjunction with stimulants, diaphoretics, etc. One of the best of the latter is spirits atheris nitrosi, administered in one-ounce to two-ounce doses, and is a very favorite medicament. Inhalations of acetous vapors and the addition of about one ounce of potassium nitrate, dissolved in the pail of drinking water, together with the employment of a nutritious and rather laxative diet, and the protection of the body from currents of air and maintenance of its thermal equilibrium by means of good woollen coverings, constitute the more ordinary treatment.

The administration of a brisk cathartic is prone to induce an apparent metastasis of the catarrhal affection from the air-passages to the intestines, and a fatal enteritis may thus ensue in the horse. The treatment, then, seems to be pretty well in accord with that in vogue in medical practice, for, notwithstanding the use of the modern antipyretics and analgesics in the recent epidemic, there seems to be a strong consensus of opinion as to the value of quinine. The complications are, of course, treated according to their kind, as they arise.

According to the recent census the population of Liverpool, England, has decreased from 552,508 in 1881 to 517,951 in 1891.

## A FEW HINTS ON THE TREATMENT OF COLAPSE.

BY J. O. MUMFORD, M.D.

SHOCK, even to extreme collapse, may be the result of a great variety of causes, so that different lines of treatment are often obviously suggested. Shock may be due, among other things, to violent mental emotion; physical exhaustion; some form of poisoning; blows on the head, chest, abdomen or genitals (not giving rise to any obvious lesion); extensive lacerations; gun-shot wounds; surgical operations; hæmorrhage, from any cause; prolonged etherization; peritoneal perforation from organic diseases; and the infinite variety of complications following disease acute or chronic.

The effect of an overdose of cocaine is a species of shock which has become familiar; and the routine cardiac stimulants seem here to be of but slight advantage. As cocaine is itself a heart stimulant, the presumption is that they act on an organ in a state of reaction from overstimulation. A most valuable antidote in these cases is strong coffee; and this would seem to be a case of paradoxical *similia similibus curantur*, as caffeine closely resembles cocaine in its action on the heart.

In the large class of cases where collapse is due to excessive hæmorrhage, the failing cardiac action can be stimulated in many different ways; yet the benefit from the ordinary drugs used is often transitory, from the fact that, though the heart's action may improve, the great centres of the brain are still insufficiently nourished. The organism has been deprived of what has been called its most important "fluid tissue," the composition of which, for the immediate purpose of stimulating its own circulation has often enough been proved of no particular importance.

Patients under these circumstances naturally attempt to supply the deficiency by drinking large amounts of water; and so long as the stomach will bear this, it should not be withheld, popular tradition and the practice of many medical attendants to the contrary notwithstanding. A large draught of cool (not iced) water will often be well borne, and the patient will experience great relief; but the custom of giving ice to suck, though immediately grateful to the sufferer, is useless for supplying what the system demands; and the constant dribbling of cold water into the stomach is very apt to bring on an attack of vomiting, as well as adding to the shock already existing.

First and most important, therefore, the indication for an increased amount of fluid in the circulation in these cases is obvious and urgent.

The method of its introduction is often a difficult one. Transfusion of blood is now pretty generally looked upon as an obsolete procedure. Suitable apparatus and a willing victim are seldom at hand; and the fluid obtained is not superior in its effects to the saline aqueous solution commonly used—a one half per cent. solution of common salt with a little bicarbonate of soda added. The procedure of infusion, however, in spite of its advantages over transfusion in speed of technique, cannot be considered a rapid operation, and often much valuable time may be lost and the patient sink beyond recovery before it can be completed. In these cases of hæmorrhage it has been my custom to give large hot enemata of a weak salt

solution as soon as possible; and if necessary, this may be supplemented by infusion. The effect of these enemata is usually immediate and striking. The solution, in the exsanguinated state of the patient, is absorbed with astonishing rapidity from the lower bowel; from the laws of endosmosis as well as from clinical observation, I should say much more rapidly than in a state of health. A quart may be given and repeated in half an hour without the slightest difficulty—the first injection being absorbed in that short space of time.

As a corollary, I may add that this observation led me to try giving nutrient enemata, largely diluted, in other cases requiring that method of feeding; using the ordinary ingredients,—peptonized beef-juice, milk and eggs, up to four or five ounces,—and adding half a pint or more of warm water. This mixture is so quickly absorbed that it can in many cases be repeated every four to six hours for days, and the thirst which is often so excessively troublesome in these cases, is thus very readily controlled.

In giving these injections the ordinary bulb syringe should never be employed. A large English web catheter attached to a short rubber tube with a funnel is the best apparatus. By this means the fluid can be introduced well up in the bowel, and can be given continuously, its force being readily controlled so as not to cause reflex expulsive movements.

In collapse the hot water enemata also serve an additional purpose, in that increased heat is brought to the abdominal viscera.

The ordinary methods of checking loss of the body's heat must never be omitted. The hot water mattress is an extremely useful apparatus, which is too seldom seen. In lieu of this, hot bottles, with light, warmed and thoroughly dry blankets should be employed liberally; the patient being kept flat on his back. The familiar procedure of raising the bed's foot so as to facilitate cerebral circulation is often useful.

Of all cardiac stimulants, alcohol probably stands first in this connection; but in giving alcohol to a patient seen soon after the accident which led to hæmorrhage, one should remember that he has probably been already overdosed, or that his injury may itself be the result of intoxication. A frequently made error of treatment is the overloading of the stomach with brandy, which is then returned, much to the patient's discomfort as well as subsequent depression. Champagne or brandy in soda are often well borne. It is a good plan, however, to add the brandy to the enema, or give it hypodermically in smaller amounts. In this way also, ether or the A. C. E. mixture may often be used to advantage.

It must not be forgotten that the injury to the patient may call for an operation, in which case the method of stimulation must be somewhat modified. It was taught, at one time, that an operation on a patient in collapse did not call for an anæsthetic, and that, therefore, stimulation should be pushed. The careful surgeon to-day, however, rarely operates upon a patient in profound collapse; preferring to wait for a rally, in which case, of course, an anæsthetic must be employed. In these cases ether is *par excellence* the drug to use, as when properly administered it is itself a stimulant. A very small amount is usually sufficient, without bringing the patient to a profound anæsthesia.

I have seen admirable results follow the exhibition

of liberal doses of digitalis — preferably by rectum or hypodermically as soon as the case is seen, before etherization; and this alone, or combined with opium in some form, will often steady and strengthen the pulse, quicken the mental faculties, and quiet the restlessness and pain, whether or not ether is given. In the former case opium is of great advantage in minimizing the amount of the anæsthetic required.

After operation under ether it is bad practice to use the same liquid again as a stimulant; and theoretically, too, alcohol is here contraindicated. As a matter of clinical experience, however, alcohol given hypodermically in small and repeated doses is seen sometimes to be of great advantage after etherization.

Of the various other drugs recommended in these cases, the value has seemed to me to be largely theoretical. Atropia is unsatisfactory when there has been large hæmorrhage, but I have found strychnia useful at times as a vaso-motor stimulant, especially in combination with digitalis. Nitro-glycerine, though theoretically contraindicated, as being a vaso dilator, often strengthens a failing heart, and is a valuable adjunct. Greig Smith, among others, speaks highly of musk by enema in infusion. The great objection to it is its expense.

I do not propose in a short paper of this kind to go into the detail of treatment for different varieties of shock, but it is well for the practical man, especially in his surgical work, to bear in mind two great classes: those cases due to, or accompanied by hæmorrhage and those without it. Of the first class, as it occurs from accidents, I have spoken. Much the same line of treatment is applicable in case of hæmorrhage from operation, except that it is well here to give digitalis and morphia previous to etherization. In such cases, too, even when there has been an inconsiderable loss of blood a warm water enema is of value, given before recovery from ether, as it allays the excessive thirst and restlessness and often seems to check the nausea.

The collapse from post-partum hæmorrhage is treated on much the same principles, after the bleeding has been checked; supplemented by frequently repeated doses of ergot or hydrastis canadensis. Excessive hæmorrhage is not a common occurrence after a properly conducted case of labor; and it must be very seldom indeed that the practitioner is called upon to tampon the uterus. In case of persistent hæmorrhage the application of a little acetic acid, five per cent., on a pledget of cotton acts promptly and effectively often, when other ordinary expedients have failed. The acid has the advantage of being aseptic as well as a good hemostatic and stimulant to the relaxed uterine muscle. In these cases, too, the alternating injection of hot water into the rectum and uterus sometimes works very well. The intra-uterine douche both stimulates the uterine muscles, and by imparting increased heat to the abdominal viscera aids the general circulation; the hot enema supplements this and the fluid being left in the gut is quickly absorbed. The temperature of the water should not exceed 112° F.

In cases of shock not accompanied by hæmorrhage it is often necessary to inquire into the special cause of the condition. Many of the cases rally spontaneously without other assistance than rest and fresh air. Other require only mild counter-irritation. Very few, however, call for cardiac stimulants, though even their administration seems, at times, of little

value. Among the most difficult cases to handle are those due to emotional causes, and the effect is proportionately enduring as the cause is impossible of removal. In many cases of shock without hæmorrhage the careful administration of atropia with nitro-glycerine acts admirably. The cardiac action is strengthened and the peripheral vessels are, at the same time dilated, with the increase of the circulation in the cerebral centres.

It is in these cases, too, that counter-irritation acts to the greatest advantage — the hot bath supplemented by a mustard leaf on the epigastrium. Irritating local applications to the mucous membranes may accomplish the same end. A man fainting from the discomfort of an overdistended bladder may be revived by the passage of a catheter even when the urine is not reached; but under ordinary circumstances the irritation of this mucous membrane is not desirable.

Brandy, by the hypodermic syringe, is unfortunately the too frequent resource in all these cases. It usually accomplishes its end, to be sure, but the not infrequently resulting abscess is a serious drawback, and the operation is often a very shocking thing to the patient's friends and most disagreeable to the patient himself if he is in a condition to appreciate the procedure.

A very useful method of getting stimulants into the stomach is to pass a small, soft catheter through the nares into the pharynx. Through this, fluids can be easily introduced into the esophagus. The manœuvre is so simple that its performance can be entrusted to any tyro. This method is most useful in some cases of collapse from acute poisoning, and in certain cases of hysteria as a substitute for rectal feeding or by the ordinary stomach tube.

In all cases of collapse the sustaining of what may prove but temporary reaction, by proper nourishment, must never be lost sight of. Few serious cases rally promptly and permanently, and the efforts of the surgeon, however painstaking, will often prove valueless, unless supplemented by intelligent, watchful and constant nursing.

## Medical Progress.

### RECENT PROGRESS IN SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

(Continued from Vol. CXXIV, No. 21, page 508.)

#### FRACURES OF THE BASE OF THE SKULL.

IN an extremely valuable series of lectures delivered before the Royal College of Surgeons of England, W. H. Battle,<sup>46</sup> has contributed an analysis of a large series of fractures at the base of the skull. He has taken all the cases that have occurred at St. Thomas's Hospital and at the Royal Free Hospital, and has tabulated and analyzed them, dividing them into non-fatal cases and fatal cases; into those involving the anterior fossa, middle fossa, posterior fossa, middle and anterior fossa, middle and posterior fossa, anterior, middle and posterior fossa. The work, as presented by the author, is admirable, and may be of some avail in diagnosing obscure cases. Regarding the diagnosis of basal fractures, Mr. Battle says:

"As a result of careful analysis of the cases con-

<sup>46</sup> British Medical Journal, July 5, 12, 19, 1890.

tained in these tables; I think we may say that, in fractures involving the *anterior* fossa of the base of the skull, the patient has usually received a blow in the frontal region, either from a weapon of some kind, or as the result of a fall; that the injury has produced bruising or wound of the part struck, and there is considerable epistaxis, and the appearance of ecchymosis under the conjunctiva, either immediately or at a later date. Sometimes the amount of blood effused into the orbit is sufficient to cause protrusion of the eye, and interference with the action of the muscles. Loss of vision may supervene in the eye of the injured side; loss of smell is rarely noticed. There may be paralysis of the third or sixth nerve. In fracture of the *middle* fossa the patient has usually fallen from a height, from a vehicle, or been knocked down in the street; and there is a wound or contusion over the parietal or fronto-parietal region. As a rule, he bleeds profusely from the ear on the side injured; there may be, however, a free, watery discharge from the first, or this may supervene on the cessation of the hæmorrhage. Facial paralysis, with or without deafness, is occasionally met with, and is an important sign of fracture; if it be present from the first, it will probably become permanent. The supervention of supuration in these cases, or the presence of middle ear disease at the time of the accident, is a most serious complication. Fractures of the base having their origin in the *posterior* part of the skull are most frequently met with in big, heavy people, and they result most commonly from a fall backwards on hard pavement from a vehicle, from a height, or down steps. There may be a contusion or wound of the part struck. The latter is seldom extensive, rarely exposing the bone. The former is often very evident; it frequently overlies the commencement of the fracture. If the middle fossa be not involved, the only reliable sign of the fracture is the appearance of ecchymosis over the mastoid process; and, as this does not usually appear for some days, great care must be taken with patients who come under notice after injuries of the occipital region, as fractures in that part of the base are very fatal. The fractures are not uncommonly followed by double optic neuritis."

Regarding the cause of death from fractures at the base of the skull, Mr. Battle says:

"I have had a table constructed (not here reproduced) showing the cause of death in 54 cases of fracture of the base. The shock of the injury proved fatal in four; that the shock of the injury, combined with that resulting from other injuries, such as fractured ribs, was fatal in six. One patient died in convulsions within the hour after admission; four with arachnoid hæmorrhage at varying periods; 32 from cerebral contusion, with laceration and hæmorrhage; three from meningitis at the end of the second week; one, aged four, from uncontrollable vomiting; while the impaction of partly digested food in the pharynx produced asphyxia in another; delirium tremens proved fatal in one case; and only one, a patient with compound comminuted fracture of the skull, died from septic disease. Thirty of the cases died within a day after admission to the hospital. The most striking fact shown by this table is the large proportion of cases dying as a result of injury to the brain, more than half of the total number; and it is of interest to observe that of the eleven cases in which the fracture of the base was strictly limited to the posterior fossa (if we include one accidentally omitted from the table)

all presented a similar condition of contused brain, with hæmorrhage as the cause of death. And I would ask you to give your attention to another fact, and that is the extreme fatality of these fractures in the posterior fossa, exactly one-half of the series of 22 proved fatal, a proportion far beyond that met with in other fractures of the base, which, as shown by these tables, is twenty-five per cent. for the anterior, and about the same for the middle fossa. In this series of cases, both fatal and non-fatal, the proportion of fractures in the posterior fossa, with regard to fractures in the other fossæ of the base, is larger than that usually observed.

"When we regard the large number of patients who die from cerebral injury with hæmorrhage from the part of the brain lacerated, the question presents itself most strongly for answer as to the advisability of using the trephine more often in an attempt to relieve them. The improved methods of operating, the slight increase of risk that is caused by the operation itself, and our enlarged knowledge as to the local condition in such cases, urge the performance of the operation, and at an early date. True, there are many factors against success, both in the condition of the brain and the general condition of the patient; but I would suggest that the cause of death is usually the presence of the blood-clot, and not the contusion of the brain. We are hardly in a position to state what extent of contusion and laceration of the frontal and temporo-sphenoidal lobes is incompatible with life. The operator must be guided by his knowledge of the effect of these injuries on the brain substance, and recollect that the fatal hæmorrhage will usually be over that part of the brain directly opposite to the part struck, and not immediately underneath it."

#### STERILIZATION OF CATGUT.

This important subject has been ably investigated by Larochette.<sup>41</sup>

"According to Reverdin, sterilization of catgut is more difficult to accomplish than is the case with any of the other materials used for suturing or ligature. He states that it is comparatively easy to destroy all the germs in catgut, if the latter is entirely free from fat, and is then submitted to a temperature of 140° C. for four hours. When the fat is not removed from the gut, the latter is fried in its own grease. For the purpose of determining the accuracy of this observation, Larochette introduced pieces of catgut into glass tubes, which were then hermetically sealed. These tubes were placed in an oil bath, the temperature of which was gradually elevated. At 90° C. the smallest catgut was so markedly altered as to be unfit for use. At 100° C. the largest size was similarly affected. For the purpose of entirely removing all fat, a quantity of catgut was then subjected to the action of ether and bisulphide of carbon. Precisely the same results followed as in the first series of experiments. Catgut deprived of its fat was then placed in a large oven, which was gradually heated. At a temperature of 100° C. it suffered no change. It was then kept for three hours at a temperature of 115° C. On removing it from the oven it was found to be slightly burned, but was still sufficiently strong to use in surgical practice. Those strands, however, which had been freed from fat by the action of ether were entirely useless,

<sup>41</sup> Lyon Medical, June 1, 1890; American Journal of Medical Sciences, October, 1890.

being rendered almost friable. Dynamometer tests applied to the catgut thus sterilized by heat showed that its resistance was but slightly lessened. This was particularly the case when the fat had not been removed. The strands were much less supple than before being sterilized by heat. Larochette considers that the sterilization of catgut by heat is perfectly practicable if the following points are carefully observed, namely, the gradual elevation of the temperature, and plenty of space for the evaporation of the water contained in the gut. After exposure for two hours to a temperature of  $140^{\circ}$  C. ( $284^{\circ}$  F.) sterilization is complete. The catgut should then be placed by means of a pair of flamed forceps, in olive oil previously boiled, and containing ten per cent. by weight of crystallized carbolic acid.

A short article on this subject by George R. Fowler<sup>42</sup> details the result of his experimentation in obtaining complete sterilization of catgut. After numerous trials he has decided that catgut treated in the following manner will resist the bacteriological test for sterilization:

The catgut is wound upon ordinary, small wooden spools, such as are used for winding cotton or linen thread, these being previously boiled in a solution of soda for a time, in order to cleanse them and at the same time remove any coloring matter. The catgut wound upon the spools is then placed in a small fruit-jar, or ground-glass-stoppered bottle, the cover or stopper being left loose, and the requisite amount of alcohol being poured over it. A pint, he states, is sufficient for sterilizing fifty metres of catgut. The small fruit-jar, or ground-glass-stoppered bottle is then placed in a water-bath, or one of the steam milk-sterilizers in common use, or any method of boiling the alcohol may be employed. This is done for one hour. The alcohol he uses is ninety-five or ninety-seven per cent. This he considers a matter of a great deal of importance.

#### STERILIZED SALT SOLUTION IRRIGATION.

Fritsch<sup>43</sup> again calls attention to the value of a sterilized hot six-tenths per cent. salt solution for irrigation or cleansing purposes in operation where previous infection of tissues is absent. This solution (temperature  $38.5^{\circ}$ ) in abdominal operations, he claims strengthens the pulse in collapse.

#### ZINC PASTE DRESSING FOR HARE-LIP.

Von Noorden, Tubingen,<sup>44</sup> has recommended the paste first introduced by Socin in 1883, as a dressing superior to others in simplicity, convenience, mechanical and antiseptic effect.<sup>45</sup> It has the quality of drying very quickly in a firm crust when exposed to the air. After completing the operation the suture line is disinfected and carefully dried. The paste then freshly prepared is applied over the whole upper lip with a brush or spatula with one or two very thin layers of cotton interspersed for support. If the wound extends into the nostril the paste should cover it throughout its extent but without blocking the nostril. It dries rapidly and forms an air-tight firmly adherent covering over which the nasal secretions run without dissolving it. It is non-irritating. The dressing is changed on the fourth to sixth day for removal of sutures. If not already loose it can be slowly cut

away piecemeal with scissors. A fresh dressing is then applied which is allowed to remain till separated spontaneously. This dressing was satisfactorily tested by v. Noorden in ten cases. It was also used for small sutured wounds of the face, herniotomies, cancer of the lip, etc.

#### METHOD OF CONTROLLING THE SUBCLAVIAN ARTERY.

W. W. Keen,<sup>46</sup> suggests the following method of controlling the subclavian artery during an operation:

A strong Esmarch bandage is selected, which is used to exert pressure on a suitable roller bandage two inches wide, that is placed above the clavicle over the position of the artery as ascertained by the touch. The elastic bandage is then passed over the roller bandage down the back between the thighs and up the front of the trunk. Every alternate turn is passed round through the opposite axilla, in order to prevent the roller bandage, which compresses the vessels, from slipping. By this means, when properly applied, one has, Dr. Keen states, an effective method of controlling the subclavian artery.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. THE ONE HUNDRED AND TENTH ANNUAL MEETING.

BOSTON, JUNE 9 AND 10, 1891.

(Continued from Vol. CXXIV, No. 26, page 637.)

#### SECTION IN MEDICINE.

DR. A. H. JOHNSON, of Salem, Chairman. DR. HENRY JACKSON, of Boston, Secretary.

DR. W. H. PIERCE, of Bernardston, read a very interesting paper on

#### TYPHOID FEVER.

The poison of typhoid fever does not originate in cess-pools, but finds there the most favorable soil for its development. The germ must undergo further change after it leaves the intestine before it can produce the disease in another patient. Dr. Pierce referred to the many cases of typhoid fever where it was impossible to make a diagnosis in the early stages. The diet of a typhoid fever patient is very important, the digestive functions being impaired; the food should be simple. Milk and the various preparations of milk are by far the best. No solid food should be given till convalescence is assured. Alcoholic stimulants are useful, but should be given only when required; they are particularly called for in the latter stages of the disease, when there is danger from heart-failure. Dr. Pierce considers the too general use of antipyretics ill-advised for and tending to reduce the temperature at the expense of the heart. Cold, in the form of cold baths and sponging, he heartily recommended, and said he had experienced great success in this line. The stools of typhoid patients should always be thoroughly disinfected.

DR. E. N. WHITTIER, of Boston, expressed great interest in Dr. Pierce's paper, and he emphasized the importance of exercising extreme care in the employment of drugs, especially those intended to reduce the temperature. The cold bath for the reduction of the temperature in a case of typhoid fever is a most excellent way. The profession seem to be gradually acquiring the knowledge of the fact that it is not the abstraction of heat that does the work, but that it produces its chief and beneficial effect by the influence on the nervous system. The statistics brought forward by those who are in favor of the cold-bath treatment are incontestable; the mortality of typhoid has been greatly reduced by its employment. Antiseptics are demanded in every case of typhoid, and a great deal depends upon their careful employment. Carbolic acid and corrosive sublimate, for the disinfection of the stools, are too dangerous to leave in the hands of the inexperienced; and in these cases chloride of lime should be substituted. We must render the contents of the small intestine as aseptic as possible, and to this end salicylin or salol can be used. This is especially useful in those comparatively rare cases of typhoid which run their course in constipation. The flushing of the colon is a good thing. It has not been Dr. Whittier's practice, for the first four weeks of a case, to give any other kinds of food than those found in milk and preparations of milk,—milk whey, peptonized milk, the albuminoids, so-called, are neither needful nor safe, and we may regret using them. Nathan Smith well remarked, with reference to the treatment of infectious diseases, to give fresh air, fresh water, and few drugs; and experience has demonstrated this to be good advice.

DR. C. C. ODLIN, of Melrose, thought that typhoid fever has gradually become milder within the past twenty years. Its type has become considerably changed. He referred to the difficulty of differential diagnosis in some cases between typhoid and other diseases, particularly cerebro-spinal meningitis. Our forefathers thought they knew how to treat typhoid when they bled and purged and salivated their patients. We believe typhoid fever is a self-limited disease, and that we can save our patient if we only can keep him alive long enough. It seemed to him that within the past few years many physicians had felt that temperature and typhoid fever were synonymous terms, and the main aim at treatment had been to pull down the temperature at all hazards. As a result, we had the treatment by cold baths, which had been alluded to; but with which the speaker had no experience. Then there were the many coal-tar preparations, antipyretic in their character, and the use of which, in his opinion, was not devoid of danger. Of course, when the temperature went very high, so as to make us fear heart paralysis, it might be necessary to occasionally give antipyretics; and he thought, on the whole, that phenacetin was the safest. The use of antiseptics in typhoid fever was called for.

DR. J. A. GAGE, of Lowell, said he had a few remarks to make regarding the prophylactic treatment of typhoid. He referred to the recent epidemic of typhoid in Lowell, and mainly attributed it to the lack of necessary antiseptic precautions on the part of the inhabitants of Lowell.<sup>1</sup> Many of the houses have privies which do not connect with sewers, and into which the dejecta of typhoid patients are thrown, and

<sup>1</sup> See Professor Sedgwick's analysis of water-supply of Lowell, with reference to this epidemic, Journal, p. 397.

in many instances there is no pretence of making the stools aseptic. As a member of the Lowell Board of Health he worked hard to abolish these privies, but with poor success. Dr. Gage insisted upon the necessity of a thorough disinfection of the stools, and he gives to every family in whose midst is a case of typhoid fever which he is called to treat, antiseptics, and sees that the stools, linen, etc., are disinfected.

Dr. J. A. JEFFRIES, of Boston, read a very instructive paper on

#### THE BACILLUS OF TYPHOID: ITS OCCURRENCE AND SIGNIFICANCE.

#### THE PRODROMAL AND EARLY SYMPTOMS OF BRIGHT'S DISEASE

was the title of a carefully prepared and able paper by Dr. C. F. WITHERINGTON, of Roxbury.

Dr. Witherington collected and tabulated the early symptoms of a number of cases from the Boston City Hospital records. Overworked business men and such, as a rule, do not look for symptoms; they have other things to occupy their attention; and this class of men do not often consult the physician in the early stage of their disease. Dr. Witherington spoke of gout and rheumatism as probable causes for Bright's disease. The early symptoms vary a good deal in different individuals. Continuous or paroxysmal dyspnoea is one of the earliest and commonest symptoms of Bright's disease. Oedema, palpitation of the heart, cough, delirium, and lumbar pain were present as early symptoms in some cases. Sometimes there is constipation, and the head feels muggy, or the patient may be irritable or morose. Insanity of Bright's disease is recognized.

Dr. GEO. B. SHATTUCK, of Boston, said: Dr. Witherington has shown us very satisfactorily the results of carefully collected statistics from the records of our largest hospital. It is, however, from the private practitioner that we should expect to get the most instruction with regard to the *prodromal* symptoms, at least, of Bright's disease. There are very few private practitioners who are in a position to give us much personal instruction in regard to this question, and those few are apt to be such busy men that they do not keep their records of this class of cases always in a way to be available. Then, again, in our time very few physicians take care of a family through a whole generation, and those physicians who take care of a family through more than one generation scarcely exist any more. Rheumatic arthritis and gout no doubt predispose to the disease, and a person who has inherited this rheumatic or gouty diathesis may, in turn, be said to be from birth, almost, subject to the prodromal symptoms of Bright's disease, and in following such an one from his early years down through his adult career into middle life we get at the real and the true lessons upon this subject. Then there are the individuals who have been exposed to poisons, such as lead and arsenic; and those patients may be suspected of exhibiting at any time the prodromal symptoms of Bright's disease.

Of course, there is a great deal in the question of increased arterial tension; it is a warning of a functional stage we ought to recognize clinically from the pulse, the finger, at least, as shown by length, persistence and incompleteness of the pulse, and after having recognized it clinically, we ought to make use of it for the benefit of our patient, by careful regulation of diet, dress and

mode of life. The sphygmograph has not justified the confidence as an instrument of precision which some clinicians were disposed, twelve or fifteen years ago, to repose in it.

Dr. E. G. CUTLER, of Boston, said: Dr. Witherington has placed rheumatism among the prodromal symptoms of Bright's disease. So far as I recollect now, it has never been my experience to see many cases where that preceded Bright's disease, outside of hospital patients. In regard to gout, we all believe it to be a frequent cause of Bright's disease. Cases of lead poisoning I have happened to see once or twice as prodromal symptoms in the production of the disease. I have also seen some cases of arsenical poisoning which were followed by chronic interstitial nephritis. In one of the cases the arsenic was administered by the cook in the family; and the case was followed up for some time. In regard to oedema, one who has examined a large number of cases for life insurance, I think, must be careful in accepting that without other symptoms as an early symptom of kidney disease. I have seen oedema of the legs frequently, particularly in persons beyond middle life, where kidney trouble was not present. Oedema of the face I am inclined to lay more stress on. In regard to the question of heredity raised by Dr. Shattuck, the life insurance companies place much importance upon the presence of certain diseases in other members of a family.

(To be continued.)

#### COLORADO STATE MEDICAL SOCIETY.

MEETING JUNE 17, 1891.

#### TUBERCULIN: THE VALUE AND LIMITATIONS OF ITS USE IN CONSUMPTION.

The following are the conclusions given by Dr. Charles Denison, in summing up his investigations of the above subject embodied in his paper read before the Colorado State Medical Society, June 17, 1891:

The cases under treatment numbered nineteen, and they are fairly classified about as follows: Five finished cases much improved or cured; five yet under treatment, favorably progressing; four favorable cases left off treatment for reasons given; five not benefited, or unfavorable cases for this method of treatment.

The following conclusions, however poorly elaborated in the body of this report, seem to me to be warranted at this stage of our investigations:

(1) Tuberculin furnishes a natural method of cure to be classed with stimulants, hypho-phosphites, chloride of gold hypodermically used, exercise, high altitudes and cold, dry air; yet it is too powerful to be indiscriminately used, and the proportion of consumptives for whom its use would be advantageous, remains to be determined.

(2) It is unreasonable to expect that tuberculin will be useful in sepsis, or any poisonous blood state other than tuberculosis.

(3) Use tuberculin not as a substitute, but as an aid to climate, and other natural methods of cure; proper food, hygienic surroundings; mountain climbing, etc., especially are high altitudes and exercise indicated, if otherwise advisable, because they favor the ventilation of lung necessary in giving tuberculin.

(4) Seek only local reactions in the affected tissues.

A high or prolonged febrile reaction is to be avoided, if possible. Use the minimum dose that will accomplish this purpose, and it is preferable to let at least a day elapse between a subsidence of one reaction and the possible creation of another. Remember that an increase from one-quarter to one-third of a milligramme may be as great for a case already reacting to the smaller dose, as an increase from thirty to forty milligrammes in a case that far advanced in the treatment.

(5) The lack of ventilation in a lung, whether caused by tuberculin already used or whether pre-existing, is a decided contra-indication to pushing the treatment, that is, according to this deficiency and the febrile state.

(6) The test for the proper ventilation of a tubercular or fibro-tubercular lung, is to be found in the comparison of the spirometrical record with the bilateral measurements of the chest and with available physical signs. A fair way to express this deficiency is to say, if the normal spirometrical record for the height is abridged one-half and the movements of the two sides are as one to two, then there is sufficient lack of ventilation in the weakest lung for extra caution as to using tuberculin at all. There is either too much elastic tissue already there, or the bacilli, if loosened by tuberculin, may not be expelled.

(7) The stage of the lung-disease has not so much to do with the question of using tuberculin at all, as has its extent and locality, the febrile course and the ventilation of the affected lung. If possible have an average daily range of temperature of less than two degrees upon which to proceed, and the patient able to be much of the time in the open air.

(8) The diagnostic value of small hypodermics of tuberculin is shown, with or without febrile reaction, in the appearance on auscultation, at suspected or affected spots in the lung substance, of a more or less decided *roughening of a previously existing broncho-vesicular respiration*, or a *high-pitched rude breathing* where before only a feeble respiration was noticed.

(9) With the appearance of any unfavorable physical signs during the course of tuberculin treatment, such as a clogged-up section of lung, or moist rales so located as to be suspicious of softening, I think it would be well to intermit injections of tuberculin and substitute those of iodine for a while, or to give temporarily syrup hydro-iodic acid compound, or to use inunctions of olate of mercury over the affected lung, until a return to the use of tuberculin is quite safe.

(10) As to permanence of effects produced by tuberculin injections, there is to me no apparent reason for expecting any more lasting results than from any other agency which will accomplish as much. I do not see any reason why bacilli should not appear again in the sputum after their cessation under tuberculin treatment, as after their cessation under climatic treatment, or the double chloride of gold injection.

It is quite probable that the effect of tuberculin is temporary. We need not look for a guaranteed immunity from lung tuberculosis, except under such other conditions of healthful living as would insure it.

In fine, tuberculin is not a remedy to be chosen for the great majority of pulmonary consumptives in preference to a proper change of climate, for it does not equal the latter; but with such a change it is an important adjuvant to the cure of a large selected class of tubercular lung diseases.

283 WASHINGTON STREET, BOSTON, MASS.

## CEREBRAL HÆMORRHAGE.

It was known to Morgagni and other of the older pathologists that cerebral hæmorrhage oftener takes place into the corpus striatum and optic thalamus than into any other part of the encephalon. Charcot's statistics show that in 301 out of 386 cases, the hæmorrhage was seated in the above mentioned region. Evidently, then, the arteries in this situation must be weaker and less able to stand exaggerated tension than in the pons, cortex, and other parts. The normal arterial wall does not readily rupture, as the experiments of Worm-Müller show. Cruveilhier and Virchow many years ago described an ampullary dilatation consecutive to atrophy of the muscular tunica as characteristic of cerebral arteries that undergo rupture in apopleptic extravasations, and still later, Charcot and Bouehard described similar lesions, under the name of miliary aneurisms, following diffuse periarteritis. These aneurismal dilatations exist in all cases of cerebral hæmorrhage, and are oftener than elsewhere seated in the arteries of the opto-striate bodies.

In response to the question, *Why* this predisposition of these arteries to miliary aneurisms, Mendel at the recent meeting of the Medical Society at Berlin (May 27, 1891), referred to the anatomical relations of these arteries. They are terminal arteries, having no anastomoses with the neighboring arteries. This, at least, applies to the basal ganglia; as for the arteries of the cortex, they present numerous anastomoses (Heubner and Mendel).

As the result of numerous personal researches, Mendel finds that the blood-pressure as measured by the manometer, is the same in the carotid and in the artery of the corpus striatum, while it is lower in the arteries of the cortex; thus, if the tension measures thirty millimetres in the carotid, it is sixteen, seventeen, or twenty-three in the arteries of the cortex. Hence, if the heart's impulse raises the tension in the arteries, this is much greater in the arteries of the corpus striatum than in those of the cortex; conse-

quently, if the arterial walls present any pathological alterations, the vessels of the corpus striatum give way much the more readily before a sudden rise of blood-pressure.

Why such ruptures rarely occur in the pons where also the arteries are terminal and come from the vertebral is explained by anatomical reasons. The vertebral artery and the basilar artery have a flexuous course, and the augmentation of the blood-pressure has for effect to cause these flexuosities to disappear, which prevents the sudden variations of tension in these arteries.

Some experiments of E. H. Weber give some light on the question why the arteries of the opto-striate bodies are the seat of military aneurisms. This experimenter has shown that in elastic tubes the sudden augmentation of pressure of the liquid which traverses these tubes has for effect not only to dilate, but also to elongate them. It may then be admitted that the augmentation of pressure in the arterial system has for its result to cause elongation of the artery of the corpus striatum, and to produce little lateral dilatations. Little by little, if these variations of pressure are repeated, the muscular tunic atrophies, the dilatations remain permanent, and the slightest exaggeration of pressure ends in causing their rupture. A certain number of hemorrhages result not from active pressure, but from venous stasis. The artery of the corpus striatum with difficulty forces its blood-column through the very narrow veins which empty into the vena galeni, while the veins of the cortex which empty into the sinuses are relatively very large.

How, asks Mendel, shall we explain the principal phenomena observed after an apoplectic ictus? We have in a certain focus an extravasation of blood, and the surrounding territory becomes the seat of a correlative anemia; this, in most cases of cerebral hemorrhage, is the cortical region. This anemia explains the loss of consciousness, the vomitings, and the convulsions.

In their application to therapeutics, Mendel thinks these considerations fruitful in hints as to the rationality of ancient and modern modes of treatment.

Bleeding can only be of use as a preventive of vascular rupture when tension is exaggerated, but how seldom is one forewarned of the favorable moment! In our day, for bleeding is substituted the ice-cap. Is this a rational mode of treatment? On the one hand, it is impossible that the action of the cold can penetrate the interior of the cranium to the source of the hemorrhage; on the other hand, if it exerts its influence on the cortex, it determines a contraction of the vessels which can only force the blood into the central parts and raise still more the blood-pressure there. The only rational treatment, Mendel thinks, is absolute rest of the body with the head elevated.

In the discussion which followed, Senator remarked that Mendel had omitted an important factor in the pathogeny of apoplexy, namely, arterio-sclerosis. As regards treatment, clinical experience has proved the

benefits of external cold. He (Senator) believes that the ice-cap reflexly excites contraction of the deep as well as superficial vessels; certainly its sedative action cannot be denied.

Virchow said that when the arteries receive an exaggerated blood-impulse, two orders of processes may develop in their walls: (1) a simple proliferation of the constituent elements, so that the walls thicken at the same time that the vessel is dilated; (2) an inflammation of the internal tunic followed by sclerosis.

These two processes may be combined, but their application to the pathogeny of cerebral apoplexy is as simple as one might think. In cases of collateral anastomoses we find serpentine dilatations about the inflexions which receive the brunt of the blood-shock; now in cerebral apoplexy, this serpentine form is rare, and we often find only one little sacular aneurism. This occurrence is with difficulty explained by the general conditions of the blood-pressure. Moreover, we sometimes find, on the surface of the cerebrum, in the pia-mater, an apoplectic focus, and, on close examination, we discover only one little military aneurism. To this, we must add that the cerebral hemorrhage is generally unilateral, while the blood-pressure is as great on one side as on the other.

Mendel in reply to Senator, said that he had intentionally neglected to speak of arterio-sclerosis, which has nothing to do directly with apoplexy. Virchow showed this in 1856, and it is also the view of Charcot.

#### ALBUMINURIA IN PERSONS APPARENTLY HEALTHY.

At the last meeting of the American Medical Association, "The Prevalence of Albuminuria among Healthy Persons" was one of the subjects discussed. Dr. William B. Davis, of Cincinnati, who took part in that discussion, has since read a paper upon this same question in its relation to life assurance, to which his position as medical director of an important life insurance company, and the fact that he addressed a meeting of the Association of Medical Directors of such companies, lend additional importance and interest.<sup>1</sup>

Dr. Davis considers at length the causes of functional albuminuria—its diagnosis, its prognosis, and finally the relation of albuminuria to life assurance. He points out that scarcely fifteen years have elapsed since the attention of the profession has been called to the circumstance that albumen may be found in the urine of persons who do not exhibit any of the general symptoms of Bright's disease, nor even any deterioration of health; and that the evidence of those fifteen years goes far to prove that these cases of albuminuria do not all end in organic disease of the kidneys. From a careful study of the information which these years have given us, and of the testimony of the most trustworthy authorities on the subject, he concludes

<sup>1</sup> Advance sheets of the New York Medical Examiner.

that the following general rules may be followed in the consideration of candidates for life assurance having albuminuria, namely:

(1) There should be nothing in the family history indicative of heredity of Bright's disease, and there should be no symptom of renal disease in the personal history except albuminuria.

(2) The candidate should be under forty years of age, in good health, and there should be no history of gout, rheumatism, syphilis, lead poisoning, nephritis, intemperance, chronic dyspepsia, or dropsy.

(3) There should be no indication of hypertrophy of heart or increased arterial tension, no accentuation of the aortic second sound, and no palpitation or dyspnea.

(4) There should be no retinal changes.

(5) The color, density and quantity of the twenty-four hours' urine should be normal, or it may be darker in color and heavier in density.

(6) The specific gravity of the twenty-four hours' urine should not be below 1.020. It may range from 1.015 to 1.030.

(7) The precipitated albumen should not exceed one-eighth of the urine.

(8) There should be a period of the twenty-four hours when the urine is free from albumen.

(9) The urine, as a rule, should contain no tube-casts. When, however, the specific gravity and quantity of urine are normal, the presence of a few hyaline casts has no serious import.

When the above conditions have been met, he thinks it safe to approve the candidate for a short endowment policy, but adds: "To a person who has passed the above gauntlet and been subjected to a rigid medical examination, this action will doubtless appear illiberal; but until the clinical significance of albuminuria in persons apparently healthy has been finally determined by observations upon one full generation, we cannot, and probably ought not, to expect life assurance companies to do any better for them."

The general sense of the discussion which followed, in which a number of examiners participated, seemed to coincide with the conclusions of the paper, and to be expressed in the statement of Dr. Frank Wells that while it cannot be affirmed that all albuminurics are uninsurable, it is only prudent to continue to consider them, as a class, impaired lives, until science has more clearly proved that albuminuria may be physiological, and hence, under certain conditions, not a bar to insurance.

"Functional" and "cyclical" albuminuria are still to be looked at askance, and as conditions which have still to prove their claims to associate with "good lives."

#### AN INTER-CONTINENTAL AMERICAN MEDICAL CONGRESS.

At the recent meeting of the American Medical Association at Washington the proposition to hold a Pan-American Medical Congress took a definite form, in the introduction of resolutions by Dr. Charles A. L. Reed, of Cincinnati. The resolutions, which were carried unanimously, were as follows:

*Resolved*, That the American Medical Association hereby extends a cordial invitation to the Medical Profession of the Western Hemisphere, to assemble in the United States in an Inter-Continental American Medical Congress.

*Resolved*, That the Committee on Nominations be and is hereby instructed to nominate one member for each State and Territory, and one each from the Army, Navy and Marine Hos-

pital Service, who shall constitute a committee, which is hereby instructed to effect a permanent organization of the proposed Inter-Continental American Medical Congress, and to determine the time and place at which the same shall be held.

A committee was accordingly appointed, which met before the Association adjourned, and elected officers, who were also constituted a special committee to draft a constitution and report the same at an adjourned meeting of the general committee, to be held in St. Louis on October 14th, when the time and place of meeting of the Congress will be decided, and permanent officers elected.

It has been generally understood that the Congress is to be held in Chicago in connection with the Columbian Exhibition, and as the establishment of a series of congresses to be limited to the profession of the Western Hemisphere, and still to be of sufficient interest to attract a fair representation of medical men from other American States, may be fairly said to be a more or less doubtful experiment, it seems essential that the first meeting should have the attraction of the Exhibition as a coadjutor. It is, therefore, unfortunate that the year of the Chicago World's Fair should be the same as that of the International Medical Congress in Rome.

If the time of the proposed Congress conflicts with the time of the International Congress in Rome, it is surely too much to expect foreign, or even many American medical men from a distance to prefer the Congress in Chicago to that in Rome. If, on the other hand, the time could be so arranged that physicians from Central and South America could attend the Pan-American Congress just before or just after that at Rome, this fact, in connection with the presence of the World's Fair, may lead to a considerable attendance.

Apart from the World's Fair, it seems doubtful whether Chicago is a sufficiently pre-eminent medical centre to justify its selection as a place of meeting.

The medical profession of the United States have always been in closer relationship to that of Europe than to that of the Spanish-speaking countries of this continent. It is, of course, to bring the latter into more intimate relations with us that the Congress has been organized, but it might seem as if anything like a close relationship were practically impossible. Although living in the same hemisphere, we are, in point of time, in customs, and in languages much nearer certain countries of Europe than we are to South America, while, on the other hand, the same may be said of the Spanish-speaking countries of America.

The United States is such a large part of North America, that, unless a large contingent from South America is likely to attend, the objects of an American Congress might be reached by admitting Canada, Mexico and Cuba to our already organized National Associations. In fact, Canada is already represented in some of them, and her representatives are by no means among the least active and valuable of the members of that Association.

## MEDICAL NOTES.

## THE POPULATION OF IRELAND AND OF LONDON.

—On April 5th last the population of Ireland numbered 4,706,162 inhabitants, of whom 2,317,076 were males and 2,389,086 females. This shows a decrease as contrasted with the previous census of 468,674, or 9.1 per cent. In 1841 the population was over eight millions, and in 1861 a little over five and a half millions. The number of families this year represents an average of five persons per family, in 1881 the average was five and two-tenths. The revised estimate of the population of London proper in the middle of this year is 4,221,452, and for the outer ring 1,435,457, making, the population of Greater London as now estimated 5,656,909.

**MEDICAL EDUCATION IN CANADA.**—The Medical Council of the College of Physicians and Surgeons of Ontario recently passed the following resolution: "On and after the 1st of July, 1892, every student must spend a period of five years in actual professional studies, except as hereinafter provided, and the prescribed period of studies shall include four winter sessions of six months each and one summer session of ten weeks; the fifth year shall be devoted to clinical work, six months of which may be spent with a registered practitioner in Ontario and six months at one or more public hospitals, dispensaries, or laboratories, Canadian, British, or foreign, attended after being registered as a medical student in the register of the College of Physicians and Surgeons of Ontario; but any change in the curriculum of studies fixed by the council shall not come into effect until one year after such change is made."

**LEGIBLE PRESCRIPTIONS.**—There are advantages in living under a paternal government, says the *British Medical Journal*, which even Mr. Herbert Spencer may be disposed to admit. The Austrian Minister of the Interior has recently issued an ordinance that the burgomasters of all communes must exercise strict supervision over the medical men practising within their jurisdiction in the matter of legibility of prescriptions. They are charged to see that every prescription is clearly and legibly written in all its parts, so that there may be no doubt as to the remedy, the dose, or the signature. If the average handwriting of Austrian medical practitioners is as cryptic in its character as that of many of their brethren in this country, it is to be feared that many worthy men in the upper, not less than in the lower, professional circles, will have to go to school again till they have at least learnt to sign their own names so that they can be read without the aid of divination.

**ILLEGAL PRACTICE OF MEDICINE ON A DEAD BODY.**—A nice point of law has lately been debated before a French Court. The question was whether an operation on a dead body by an unqualified person came within the meaning of the enactment forbidding the illegal practice of medicine. It appears that a pregnant woman had just died, the cause of death not

being stated. The curé of the village, who had been with her in her last moments, induced a neighbor who was in the room to perform Cæsarean section on the corpse with the view of saving the child. The operation was successful; but the operator was brought before the magistrate, and fined fifteen francs for having been guilty of illegal practice of medicine.

## NEW ENGLAND.

**THE SEA-SHORE HOME**, mainly for intestinal diseases of infants, which since 1878 has been situated in Winthrop, Mass., and opened during the summer months, cannot be opened this year on account of the opposition of the residents of Winthrop.

**HARVARD MEDICAL SCHOOL, CLASS OF 1891.**—At the Harvard University Commencement, June 25, sixty-three candidates received the degree of M.D. Of these forty-six had taken the regular three years' course, and seventeen the four years' course. Of the latter, eleven received also the degree of A.M. According to the catalogue for the year 1890-91, the number of students in the Third Class was seventy-two, and in the Fourth Class twenty-six.

**THE HARVARD MEDICAL SCHOOL AND THE UNIVERSITY CREW.**—It is noticeable that the Harvard Medical School furnished one of the best of the oarsmen in the winning crew at the recent race at New London, and this fact is regarded by some at once as an indication of the liberality of medical studies, and of the importance of having a medical school attached to a university. It is said that arrangements were made to allow him to take his examinations on the banks of the Thames, but this report is not true.

**MEDICAL DEPARTMENT OF YALE UNIVERSITY.**—The graduating exercises were held in Battell Chapel, on June 23. The annual address in medicine, delivered by Dr. John S. Billings, U. S. A., is published in the last and the present issue of the *JOURNAL*. Fifteen members of the graduating class received the degree of M.D.

**MAINE MEDICAL SCHOOL.**—At the graduating exercises at Brunswick, June 24, twenty-eight candidates received the degree of M.D.

## NEW YORK.

**ACCIDENT AT THE COLUMBIA SCHOOL OF MINES.**—A sad accident occurred at the School of Mines of Columbia College on June 25th, by which Prof. John L. Northrop, Instructor in Zoology and Paleontology, received fatal injuries, and two juniors were seriously burned. Professor Northrop had occasion to go to the cellar to get some alcohol for the preservation of specimens, and the head janitor and engineer of the buildings with an assistant janitor accompanied him, each bearing a denijohn. The barrel of alcohol having been turned on its side, he lighted a gas jet jutting out from the wall, and proceeded to draw out the bung; when a terrific explosion followed. It is supposed that the fumes of the alcohol escaped and were ignited by the gas, the bar-

rel containing the alcohol having been placed near some steam pipes, and having been subjected to more or less heat for a considerable time.

**A CASE OF TETANUS.**—A patient aged forty-four years died at the German Hospital on June 22d, from tetanus, which is believed to have been caused by the extraction of three upper teeth.

## Miscellany.

### A LAW FOR THE DETENTION OF CERTAIN PERSONS WITH SYPHILIS.

THE Massachusetts Legislature passed the following act just before it adjourned, so that it is now the law of the State:

**SECTION 1.** Any person who is confined in, or an inmate of, any State penal or charitable institution, a common jail, house of correction or municipal or town almshouse, who shall have the disease known as syphilis, shall at once be placed under proper medical treatment for the cure of such disease, and when in the opinion of the attending physician it is necessary for the proper treatment thereof, or that such disease is contagious, so as to be dangerous to the health and safety of other prisoners or inmates in such institution, the persons under treatment shall be isolated from such other prisoners or inmates until the contagious stage of such disease has passed, or until the time when in the opinion of the attending physician such isolation is unnecessary.

**SECT. 2.** When at the expiration of the sentence of any person who is confined in, or is an inmate of, any of the institutions named in section one of this act, such person shall then have the disease known as syphilis in its contagious or infectious symptoms, or in the opinion of the attending physician of such institution, or of such physician as the authorities thereof may consult, would cause the discharge of such person to be dangerous to public health and safety, such person shall be placed under proper medical treatment, and kept and suitably cared for as provided in section one of this act, in the institution where he has been confined, until such time as in the opinion of the attending physician such contagious and infectious symptoms shall have disappeared, and the discharge of the patient shall not endanger the public health. The expense of his support not exceeding three dollars and fifty cents a week shall be paid by the city or town where he has a legal settlement, after notice to the overseers of the poor of such city or town, or, if he is a State pauper, after notice to the State Board of Lunacy and Charity, of the expiration of his sentence, and of his condition. [*Approved June 11, 1891.*]

### AN OBSTACLE TO SCIENTIFIC RESEARCH IN ENGLAND.

In a dispatch, dated June 6th, the London correspondent of the New York *Times* says: "The principal biologists and scientists of England, headed by Lubbock, Lister, Lockyer, Playfair, Roscoe and others, to the number of one hundred and fifty, and backed by strong letters from Huxley and Tyndall, yesterday waited on Sir Michael Hicks Beach, President of the Board of Works, for a second time, to beg that a license be found for the British Institute of Preventive Medicine, and for a second time met with a refusal. Their eloquent speeches laid stress upon the national disgrace of a situation in which English students of bacterial growths were compelled to go to

Paris, Berlin, and Vienna to study their science, and intelligent inquiry and experimental research were forbidden on English soil, as if it were an impious thing to seek for wisdom in the science of saving human life. Sir Michael Hicks-Beach gave an evasive and roundabout reply, which the London *Times* editorially translates as meaning that the anti-vivisectionists have many times more votes in England than all its men of science put together. English laws pay great attention to conserving the rights of rich men to breed hares, rabbits and game birds for annual slaughter and maiming by shooting parties, but they sternly punish a man of science who chloroforms one of these rabbits for purposes of experiments having no earthly purpose but to increase knowledge as to saving human life. But without these grotesque paradoxes this wouldn't be England."

### IS MALIGNANT PUSTULE AN ACCIDENT?

SIMILAR questions have been discussed in different courts, suit being brought to compel accident-insurance companies to recognize different forms of septic infection as an accident. In a recent trial in Albany a case was tried in which a man who had a pimple in such a company in some unknown way became afflicted with a malignant pustule, which formed on his lip and from the effect of which he died.

The reasoning of the plaintiff's attorney was, that the pustule was the result of an external injury, accidentally received; that the pustule, which fastened on his lip, came suddenly from the outside; it was not a disease, and death was therefore effected through accident.

The facts proved were these: That car-loads of hides frequently passed the railroad station where the insured was employed, and that a large number of cattle are brought there and slaughtered in the vicinity.

There was no direct proof that the deceased ever came in immediate contact with the hides or flesh of those animals or swallowed anything affected. Several physicians testified, among them F. A. Harris, M.D., of Boston, to the effect that a case of malignant pustule is not a disease, in the strict sense of the term, but a pathological condition of the system, caused by the accidental infliction of diseased or putrid animal matter, infested with bacteria or anthrax bacilli upon the thick skin of the lip, whence the bacilli multiply and are diffused through the system. In speaking of it he said that there had been noted epidemics of the disease.

The defence claimed that an epidemic disease was inconsistent with an accident theory. Also, that a pathological condition is not an accident in a legal sense. As it was also claimed that it was a carbuncle, the judge charged the jury that it was a carbuncle, the plaintiff could not recover; but that if it was a malignant pustule, he could. The verdict of the jury was conclusive that it was a pustule. A verdict was given for the plaintiff.

In the Court of Appeals the principal case relied on as a precedent by the plaintiff was a recent one in which a guest at a hotel died from the involuntary inhalation of illuminating gas while asleep. This had been decided to be an accident within the meaning of an accident-insurance policy.

<sup>1</sup> Brooklyn Medical Journal, June, 1891.

The Court of Appeals divided in this case on the question involved, Judge Peckham leading the majority, including also Judges Andrews, Earl, Finch and Gray; while Judge O'Brien wrote a dissenting opinion, which was concurred in by Chief Judge Ruger. The judges on both sides considered the Paul case, Judge Peckham arguing that the latter case was like death by drowning; that it did not produce a disease, but sudden death without disease and from causes without the person or control of the sufferer; that from the evidence of the expert physicians called for, the plaintiff showed clearly to his mind that death from pustule was regarded generally by the medical world as death from disease; that the definition given by them as to the difficulty being "a pathological condition of the body and not a disease, is upon these facts entirely too fragile to have a recovery upon."

Judge O'Brien considered in the dissenting opinion, that the case was identical in principle with the "Paul" case and "that an infliction of animal virus by some exterior force or power" "was a bodily injury effected through external, violent and accidental means."

In this case, although the judges of the court of last resort were divided, the view of the majority of the court is that the cause of death, while in its nature somewhat accidental, was yet from a disease; that a recovery could no more properly be had than if the insured had inadvertently passed through a hospital filled with persons sick with scarlet fever or small-pox, and had contracted by infection either of those diseases. It is therefore decided in the State of New York that death from malignant pustule, contracted by contact, is not an accident as against an accident-insurance company.

### SYPHILIS OF THE LUNG.

IN view of the interest at present taken in this subject, and in connection with the paper by Dr. T. E. Satterthwaite, recently published in the JOURNAL, a paper by Dr. W. T. Councilman,<sup>1</sup> of Johns Hopkins University, on the subject is especially interesting.

After going over the history of the subject, Dr. Councilman describes fully two typical cases of syphilis of the lung, which died at the hospital. In one, especially, the extent and acuteness of the lesions offered the most favorable opportunity for the study of the process. In concluding the author says that it is interesting to find that the essential process in the production of gummata in the lung is a pneumonia with fibrinous exudation, accompanied by fibrous thickening of the alveolar walls, the whole undergoing caseation. It would seem that the gummata were produced where the action of the virus was most intense. Necrosis of the tissue takes place before there is time given for the development of connective tissue. The large gummata which were surrounded by the connective tissue had sharp edges, and there seemed to be no advance of the necrosis. The smaller one, which were surrounded by the acutely-altered lung with exudation in the alveoli, were increasing by an extension of the necrosis. Where the action of the virus was less intense there was time given for the development of connective tissue, which in some

instances seemed to grow into the altered lung from the fibrous tissue around the arteries and bronchi. In other instances the connective tissue apparently developed from the walls of the alveoli.

The close analogy between tuberculosis and syphilis of the lung is shown by the formation of the gumma, being essentially a caseous pneumonia. The chief lesions in the tuberculous lung are the results of a caseous pneumonia, but there is a wide difference in the nature of the processes. The tuberculous caseous pneumonia is the direct action of the tubercle bacilli on the tissue. The exudation is almost entirely cellular, and the result is a mass of dead cells which can undergo no further change except a liquefaction of the cells themselves or the substance between them, as the result of either the further action of the tubercle bacilli or other organisms which have entered the tissue. In the gumma the primary process is the atrophy of the alveolar walls, due most probably, to a hyaline degeneration of the capillaries. The whole thing, the epithelial cells within the alveoli, the vessels and the alveolar walls, all gradually undergo the hyaline metamorphosis and become changed into a dense solid mass of hyaline. This hyaline seems to be one of the most resistant substances, and when once formed shows no more tendency to undergo further change than does the closely related amyloid substance. The author considers that there is no such condition as syphilitic phthisis. In the syphilis of the lung there is only the production of connective tissue and the dense hyaline gummata. There is an entire absence of the ulcerative processes which we find in tuberculosis. Instead of a caseous bronchitis, with destruction of their walls, there is the same process of connective tissue formation in the bronchi leading to their obliteration that we find in the alveoli. There may be bronchiectases produced by effects of the contraction of the fibrous tissue which has formed around the neighboring bronchi. In some of the other cases reported there were cavities described with perfectly smooth walls, which were almost certainly bronchiectases. One cannot make much of the cases reported. Most of them were published before the discovery of Koch, when our means for diagnosing tuberculosis were not so accurate as they are now. A case was recently reported by Potain of mixed syphilis and tuberculosis. The author regarded this as an attack of the tubercle bacilli on the syphilitic product.

In both of the cases reported sections were stained and examined for tubercle bacilli, but in neither case were any found. The important point which has come out in this investigation, is the hyaline degeneration of the capillaries. It would not do to claim this as a special effect of the syphilitic virus in all syphilitic lesions, but in the lung it certainly seemed to be the primary lesion. The mode of formation of the gummata by a pneumonia, with a termination in necrosis, is also interesting, because in this way most of the tuberculous lesions in the lungs are formed. The hyaline degeneration of the capillaries, of the cells in the exudation, and of the necrotic masses, would seem to be a special feature in syphilis. Another feature which was most prominent was the absence of leucocytes in the exudation, although all the conditions which they usually accompany seemed to be present. It is probable that the hyaline and thickened vessels offered a greater impediment to their exit.

<sup>1</sup> The Johns Hopkins Hospital Bulletin, No. 11, 1891.

## THERAPEUTIC NOTES.

**SPASM OF THE GLOTTIS.**—Sir Morell Mackenzie finds that by exciting a rival reflex, the laryngeal spasm is at once overcome. By exciting a paroxysm of sneezing, immediate relief is procured. This is best done by the inhalation of a pinch of snuff into the nares, or pepper may be used in the same way. It is sometimes possible to produce sneezing by tickling the nasal mucous membrane.

**ECZEMA OF THE ANUS AND GENITAL ORGANS.**—Lustgarten advises the following ointment:

R Oleate of cocaine . . . gr. xij to xxiv.  
Lanolin . . . . . 3 ij. M.  
Olive oil . . . . . 3 ij. M.

Apply twice daily, and after each application powder the affected part with an absorbent powder.

**IRRITATING EYE-WASHES.**—Franke<sup>1</sup> calls attention to the fact, that the instillation of solutions of atropin, eserine and cocaine into the eye frequently gives rise to acute conjunctivitis. The reason of this is that these solutions are not antiseptic and generally contain mould or fungi. If these remedies are added in the desired proportion to a 1:10,000 solution of bichloride of mercury, they will be kept antiseptic for an indefinite period, and not give rise to any irritative symptoms.

**STYRONE IN CHRONIC PURULENT OTITIS MEDIA.**—Cheltoff<sup>2</sup> ascribes great value to styrene in the treatment of middle-ear disease. Very good results were obtained by syringing with the following:

R Styrene . . . . . gr. xx.  
Alcohol . . . . . 1 3 j. M.  
Sig. One part of the above to 20 parts of water.

**ICHTHYOL.**—Uuna recommends the use of this substance in the form of a varnish, which may be painted on to the skin:

R Ichthyol } . . . . . 55 40 parts.  
Starch } . . . . . 1 part.  
Albumen (in solution) . . . . . 100 parts. M.  
Water . . . . . 100 parts. M.

Mix the starch with the water, then add the ichthyol and the albumen.

R Ichthyol . . . . . 50 parts.  
Starch . . . . . 100 parts.  
Carbolic acid . . . . . 5 parts.  
Water . . . . . 45 parts. M.

Dissolve the ichthyol and carbolic acid in hot water, and add the starch.

**ERYSIPELAS.**—Cayet<sup>3</sup> has obtained the best results by spraying the following solution on to the affected parts three times a day for about a minute:

R Hydragryl chlorid corrosivi } 55 gr. xxiv.  
Acid citric } . . . . . 3 ij.  
Alcohol . . . . . 3 v. M.  
Etheris . . . . . 3 v. M.

**SULPHATE OF COPPER IN OBSTETRICS.**—Tarnier<sup>4</sup> has for some time been using a five per cent. solution of sulphate of copper for washing out the uterus and vagina after delivery, and is very well satisfied with the results. From control experiments made with streptococci and staphylococci, and from his clinical experience he believes that he has proved that in this substance we have a readily obtainable, cheap, very soluble, relatively non-toxic, and an unusually active

disinfectant; although it is not entirely free from disadvantages. In cases where corrosive sublimate is contraindicated, sulphate of copper should, he thinks, have the preference over every other antiseptic.

## Correspondence.

## THE EFFECT OF TOBACCO ON PREGNANCY.

CHICAGO, June 15, 1891.

MR. EDITOR:—I would like an expert opinion in the following somewhat unusual case. A married lady friend of mine, who occasionally does me the honor to consult me upon obstetric problems of various kinds is now in the second month of pregnancy with her first child. She is thirty-two years of age, married two years, very anxious to bear healthy offspring. Since her marriage she has acquired the habit of indulging in a quiet smoke, with or without her husband, but entirely with his approval. Smokes about three small pipes of mild tobacco a day. Over-indulgence—say a large pipe—produces nausea; cigars produce violent nausea. But within her usual limit the practice seems beneficial to her. She is of the nervous-sanguine temperament, very excitable, and small doses of the fragrant weed “settle her nerves,” to use her own expression. The practice has become a habit.

(1) What would be the effect upon the health of mother and embryo, especially the latter?

(2) Should the practice, of necessity, be given up during pregnancy?

(3) What would be the effect upon lactation? Opinions will greatly oblige PHARMA.

N. B. The patient spoken of above has a slight (compensated) mitral regurgitation, but has not suffered from it recently.

[We have had no personal experience which would warrant our giving an expert opinion of this case; but the well-known experience of Spanish women would seem to indicate that tobacco does not necessarily exert any untoward effect on the gentler sex. We would answer the questions propounded, namely:

(1) It does not seem reasonable that tobacco, used as moderately as by the woman in question, would produce any ill effect on either mother or embryo; indeed, it is not unlikely that in the above case the effect of the weed is beneficial to the mother.

(2) No; certainly not so long as there is no apparent ill effect.

(3) Probably no effect.

Ed.]

## METEOROLOGICAL RECORD.

For the week ending June 20, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Baro- meter.	Thermom- eter.	Relative humidity.	Direction of wind.	Velocity of wind.	We'th'r.	Rainfall in inches.

Deaths reported 3,516; under five years of age 1,556; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 714, acute lung diseases 355, consumption 334, diarrhoeal diseases 264, diphtheria and croup 107, typhoid fever 74, scarlet fever 66, measles 55, whooping-cough 26, cerebro-spinal meningitis 17, malarial fever 12, erysipelas 12, puerperal fever one.

From scarlet fever New York 35, Brooklyn 12, Philadelphia 10, Chicago 5, Baltimore 4, Milwaukee and Lowell 1 each. From measles New York 16, Chicago 6, Brooklyn 5, Cincinnati 2, Philadelphia, Boston, Pittsburgh, Portland, Worcester and Lowell 1 each. From whooping-cough New York 9, Philadelphia, Brooklyn and Pittsburgh 1 each, Milwaukee 2, Chicago, Baltimore and Cleveland 1 each. From cerebro-spinal meningitis Chicago 8, Washington 3, Worcester 2, New York, Brooklyn, Milwaukee and Gloucester 1 each. From malarial fever New York 3, Brooklyn 2, Pittsburgh 1. From erysipelas New York 5, Chicago 1, Brooklyn, Boston and Lowell 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,288,441, for the week ending June 6th, the death-rate was 28.3. Deaths reported 5,102; acute lung diseases (London) 547, whooping-cough 152, measles 85, diarrhoea 28, diphtheria 35, fever 25, scarlet fever 23, small-pox (London) one.

The death-rates ranged from 16.5 in Norwich to 48.5 in Blackburn, Bradford 29.1, Hull 17.8, Leeds 24.3, Leicester 24.4, Liverpool 35.5, London 27.0, Manchester 35.7, Nottingham 21.6, Sheffield 18.9, Sunderland 21.8, Wolverhampton 35.9.

In Edinburgh 24.5, Glasgow 27.9, Dublin 20.1.

**OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF MEDICAL OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 20, 1891, TO JUNE 25, 1891.**

By direction of the Acting Secretary of War, the leave of absence on surgeon's certificate of disability, granted Major J. H. PATZKE, surgeon, in S. O. No. 99, May 1, 1891, from this office, is extended two months on surgeon's certificate of disability. Par. 15, S. O. 112, A. G. O. June 22, 1891.

By direction of the Secretary of War, Captain WILLIAM C. BOWEN, assistant surgeon, will, upon the final abandonment of Fort Davis, Tex., report in person to the commanding officer Jack on Barnett, Tex., for duty at that post. Par. 1, S. O. 139 A. G. O. June 18, 1891.

**OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 27, 1891.**

Surgeon J. H. HALL, from Naval Station, New London, and to Naval Hospital, Chelsea, Mass.

Passed assistant surgeon L. W. ATLEE, from nautical school-ship "Saratoga" and wait orders.

Passed assistant surgeon J. M. STEELE, ordered to nautical school-ship "Saratoga."

Assistant surgeon G. A. LUNG, ordered to Naval Station, New London, Conn.

Assistant surgeon J. E. PAGE, from Naval Hospital, Mare Island, and to the "Independence."

Assistant surgeon M. R. PIGOTT, from U. S. Receiving-ship "Independence" and to Naval Hospital, Mare Island, Cal.

Assistant Surgeon J. G. FIELD, detached from U. S. S. "Omaha" and granted three months' leave of absence.

FREDERICK GRATTON BRATHWAITE, of Stamford, Conn., commissioned an assistant surgeon in the Navy, June 22, 1891.

**OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING JUNE 27, 1891.**

HAMILTON, J. B., surgeon, ordered to Washington, D. C., on special duty, June 9, 1891.

GEDDINGS, H. D., assistant surgeon, ordered to New York, N. Y., on special duty, June 13, 1891. Ordered to Washington, D. C., on special duty, June 26, 1891.

WERTENAKER, C. P., assistant surgeon. When relieved at Galveston, Texas, to proceed to Chicago, Ill., for duty, June 23, 1891.

SMITH, A. C., assistant surgeon. Relieved from duty at New Orleans, La.; ordered to Galveston, Texas, June 23, 1891.

STIMPSON, W. G., assistant surgeon. Ordered to New York, N. Y., for temporary duty, June 12, 1891.

ROSENAU, M. J., assistant surgeon. When relieved at Chicago, Ill., to proceed to New Orleans, La., for duty, June 23, 1891.

**SOCIETY NOTICES.**

THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS will hold its fourth annual meeting at the New York Academy of Medicine, 17 West Forty-third Street, in the City of New York, Thursday, Friday and Saturday, September 17, 18 and 19, 1891, under the presidency of Dr. Adrian H. Wright, of Toronto. All physicians interested in the discussion of subjects pertaining to Abdominal Surgery, Obstetrics, and Gynecology, are invited to attend without further formal notice. By order of the Executive Council.

WILLIAM WARREN POTTER, M.D., Secretary.

SECOND TRIENNIAL SESSION OF THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.—The Committee of Arrangements announces under date of June 24, 1891, that the arrangements are sufficiently advanced to insure the success of the Second Triennial Session of the Congress of American Physicians and Surgeons, which will be held in Washington, D. C., during the 22d, 23d, 24th and 25th of September, 1891. The sessions of the Congress will be held in the Main Hall of the Grand Army Building, 1412 and 1414 Pennsylvania Avenue, from 3 to 6 p. m., daily. The President's Address will be delivered in the Lecture Hall of the National Museum, Wednesday, September 23d, at 8 p. m., followed by the Reception of the President, from 9 to 10 p. m. Order of Executive Committee. The Army Medical Museum will be open the same evening. The Congress will be composed of the members of the constituent societies and invited guests. A registration fee of five dollars will be required of every member of the constituent societies who may register; invited guests will not pay the fee. The evenings of Tuesday, September 22d, and Thursday, September 24th, are left to the societies. Members of the American Surgical Association and of the Association of American Physicians will conjointly entertain their foreign guests at dinner at the Arlington Hotel, Thursday, September 24th, at 8 p. m. The American Gynecological Society has also arranged for a dinner at the Arlington Hotel, Thursday evening, September 24th. The American Pediatric Society give a dinner September 24th.

SAMUEL C. BISKAMP, M.D., Chairman.  
1515 I Street, N.W., Washington, D. C.

PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

BY HAROLD C. FENST, M.D.,  
*Instructor in Bacteriology at the Harvard Medical School.*  
 (Continued from No. 1, page 7.)

THE first set of cases, then, to which I wish to call your attention is that in which the pulmonary lesions were the most prominent; and in this, I have twelve to account for. The histories are as follows:

## SECTION I. — PULMONARY. — CASES I-XII.

CASE I. Admitted December 6, 1890. Service of Dr. G. G. Tarbell. Born in Prince Edwards Island, about twenty-two years old, single, table-girl. Maternal grandfather and brother died of phthisis. Was always well until one year ago. The disease began, following an attack of influenza; loss of weight and appetite; night sweats; pain in the right side, diarrhoea last summer. General health fair; no hæmorrhages; is well developed; somewhat emaciated and pale; poor strength, poor nutrition and appetite; sleep good except when coughing; skin moist; suffers from chills, fever, night sweats; temperature 98.4° pulse 108; respiration 32; breathing shallow, with considerable cough; thick, yellow expectoration; no record of bacilli at entrance; suffers from pain in the right chest; stools negative; urine December, 1890, high, acid, 1017, no albumen; abdomen normal. Physical examination on December 6th, shows the vocal resonance increased at the right summit; dullness over right front and back; bronchial respiration and bronchophony in the upper half of the right front and back; also numerous fine and coarse moist râles at the same place; respiration more markedly bronchial over a small area of the right back between the scapular and the vertebral column; respiration on the left side harsh only.

January 1st. Dose, .0004 gm. Dizzy and headache in the afternoon; diminished appetite; slight nausea; increase of cough; increase of sputum (mucopurulent); signs in the chest same as yesterday.

March 10th. A slight shivering at night. Upon the 13th allowed to go home for a day or two, and did not return.

*Summary.*—Number of injections 16; amount used 41 mg.; highest dose 4.5 mg.; highest temperature 104.4° after the seventh injection of two milligrammes. Not relieved.

CASE II. Lives in Boston. Admitted December 13, 1891. Service of Dr. G. G. Tarbell. Born in New York, thirty-one years of age, single, peddler. Mother died of phthisis. Was always well until one year ago. Slight cough was the first symptom. General health fair. Hæmorrhage of from two to three cupfuls in the summer of 1890, and a second one eight weeks ago, lasting for three days. Is well developed; pale; poor strength; emaciated looking. Fair appetite and sleep. Herpes on chin, and left face. Heart and circulation negative.

On December 31st, there was dullness to the third rib. Bronchial respiration, with slight bronchophony; a few fine moist râles in the upper right front. Respiration was harsh on the right side of the chest.

The left front, and both backs were negative, except that the percussion note, was slightly higher on the upper right back than on the left.

January 1, 1891, the first injection of .0004 gm. Slight diarrhoea, probably due to jellies and fruit.

March 30th. Went out for a week. Bacilli, No. 5. Weight 105½ pounds.

April 9th. Reported. There was no vacant bed, and so not admitted.

*Summary.*—Number of injections, 33; amount of material used, 252.8 mg.; highest dose was 16 mg.; highest temperature was 103.6°, after the thirty-third injection of 4.8 milligrammes. Not relieved. For a time patient gained weight, and the bacilli disappeared from the sputum; they returned, however, and weight diminished also.

CASE III. Lives in Boston. Admitted December 29, 1890. Service of Dr. G. G. Tarbell. Born in Germany, thirty-two years old, married, tailor. Father died of some throat trouble. Date of commencement of disease four years ago, after an attack of bronchitis. Two years ago caught cold, and was in bed with lung fever. General health fair. Hæmorrhage six weeks ago; spit up a cupful of bright red, frothy blood. Well developed (anæmic); fair strength; good nutrition; fair appetite; good sleep; stools negative; second pulmonary sound accentuated; severe night sweats; temperature 98.5°, pulse 88, respiration 26; expectoration yellowish and white, sometimes streaked with blood. Troubled with cough, hoarseness and sore throat, which persisted although he had been at work. July, 1890, entered the Consumptives' Home, where he has made some general gain.

Physical examination shows that the chest moves equally with respiration; there is a depression above each clavicle. Percussion is dull at the right apex, front, and at the left base back. Respiration is harsh in the upper half of the right front, bronchial at the right summit, with numerous fine and medium moist râles at the right apex; also fewer in number throughout the right chest; voice-sounds slightly increased on the right; on the left, on cough only, a few fine moist râles at the apex; respiration rather harsh; voice-sounds slightly increased, with a few fine, moist râles.

January 1st. Dose, .004 gm. Slight headache at 1 p. m.; increased pain over the left apex, the right front and the left base.

April 1st. Bacilli, No. 7. Weight 167½ pounds.

*Summary.*—Number of injections, 35; amount used, 227.8 mg.; highest dose, 12.2 mg.; highest temperature, 101.8°, after the thirteenth injection of 4.8 mg., this temperature being exclusive of the florid stage of the disease. Not relieved. Made an apparent gain in general condition, and weighed seven pounds more at the end of treatment; but the bacilli did not disappear from the sputum.

CASE IV. Lives in Boston. Admitted January 2, 1891. Service of Dr. G. G. Tarbell. Born in New Brunswick, thirty-seven years old, married, teamster. Chancere eighteen years ago; gonorrhoea three times, last three years ago. Pneumonia in 1885. Had a cough ever since. General health, fair. Well-developed; fair strength, fair nutrition, good appetite and fair sleep; skin normal, except at lesions; heart and circulation negative; no chills, no fever, no night sweats; cough less severe within the last two months; expectoration slight, whitish; stools negative; urine pale, alkaline, 1009, no albumen; abdomen nega-

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1891.

tive. About one year ago, had a large, round swelling appear just below the larynx, which increased until it became of the size of an English walnut. It was then opened in out-patient department. Other similar swellings have appeared upon the neck, some of which have been opened. Skin reddened and indurated, and lies in folds about the neck, with deep depressions. No discharge; not painful or tender; no difficulty in swallowing. Slight dullness, and a few moist râles at the right apex, front and back.

January 3d. Dose, .0006 gm. Some oozing from the sinuses on the neck; one fold much increased and tense. The areola surrounding the sinuses slightly red.

April 13th. Treatment omitted.

**Summary.**—Number of injections, 36; amount used, 264.5 mg.; highest dose, 14 mg.; highest temperature, 101.6°, after ninth injection of .004 gm. Discharged, relieved; because the bacilli had been gone from the sputum most of the time, and he had gained nearly ten pounds in weight. Lesions of neck not improved.

**CASE V.** Boston. Admitted December 31, 1890. Service of Drs. Forster and Blake. Born in Ireland, thirty years old, single, sailor. Family history negative. General health fair. Tongue tremulous, coated; face flushed; pupils dilated. Well-developed; good strength and nutrition; poor appetite and poor sleep; heart and circulation negative; pain in both chests; urine normal, acid, 1020, no albumen; abdomen negative. Was in City Hospital from December 12th to 23d, with phthisis; discharged relieved. Comes in alcoholic; has been drinking. Complaints of shortness of breath and pain in both chests, nervousness; cannot sleep. Examination shows dullness at the left apex to the second rib in front and the second behind. Broncho-vesicular breathing; increased voice and fremitus; and many fine, moist râles at the right apex; breathing harsh.

January 5th. Dose, .0005 gm., given by Dr. Forster. Slight dullness at both apices. On the right side, râles to the third rib in front and the spine of the scapula behind. On the left side, râles to the seventh rib in front and the left scapula behind. Respiration very slightly broncho-vesicular.

February 14th. Left apex: dullness to third rib in front; increased voice and fremitus; moist râles on deep breathing. Right apex; less dullness; fine, crepitant râles at end of inspiration. Patient discharged to-day for repeated profanity and disobedience to the rules.

**Summary.**—Number of injections, 19; amount of material used, 93.4 mg. Highest temperature 102°, on the sixth day after the sixth injection of 3.2 mg. Not relieved. Gained in weight. Bacilli never found.

April 25th. Patient drinking hard.

**CASE VI.** Lives in Boston. Admitted January 6, 1891. Service of Dr. G. G. Tarbell. Born in Pennsylvania, twenty-five years old, single, a physician. Both father and mother died of phthisis, and eleven out of thirteen children. Had diphtheria at fourteen. Disease began three years ago, following a cold. General health fair; menstruation regular; had a hemorrhage two years ago. Good development, but anæmic; fair strength; good nutrition, appetite and sleep; heart and circulation negative; no chills; slight fever; occasional night sweats; moderate cough; slight expectoration; bacilli found in the spu-

tum at various times; slight pain; stools normal; urine negative, acid, 1022, faint trace of albumen, sediment consisting of leucocytes and bladder epithelium; abdomen negative. Caught cold three years ago, and had a cough for some time; then was better till two years ago; then got another cold, followed by a cough and a hemorrhage of about one-half a cupful. Has coughed more or less ever since; has not lost much flesh or strength. Spent four months in Denver in the winter of 1889; but was not so well as in Boston. Had an attack of pleurisy there; returned to Boston last spring, and has been at work ever since.

Examination shows a well-developed and nourished girl; dullness at the right apex, front and back, as far as the third rib. Vocal resonance increased over the upper right third of the back and front; bronchophony with bronchial respiration over the upper third of the right front, with fine, moist râles; also fine, moist râles in other parts of the right chest and the apex of the left. A few râles in the middle of the left back. Heart and abdomen negative.

January 7th. Dose, .0008 gm. Slight headache; good sleep; slight increase of cough; bacilli in the sputum, Nos. 5 and 6. Weight 124½ pounds.

April 9th. Treatment omitted for the purposes of this paper. Bacilli, No. 3.

April 25th. Patient seen, and claims to have felt a great benefit from the treatment. Bacilli in the sputum in enormous numbers.

**Summary.**—Number of injections, 38; amount used 347.6 mg.; highest dose 10 mg.; highest temperature 101.4°, after the thirty-third injection of six mg.

May 2d. Not improved. Gain in weight steady up to end of treatment, but slight.

**CASE VII.** Lives in Charlestown. Admitted January 7, 1891. Service of Dr. Forster and Blake. Born in Ireland, thirty-two years old, longshoreman. Family history good. Gonorrhea fifteen years ago. Disease commenced two months ago; cough and expectoration. General health good. Alcohol and tobacco. Slight haemorrhages from time to time. Well-developed; good strength; fair nutrition, appetite and sleep; heart and circulation negative; occasional night sweats; dyspnea for a few weeks; slight cough; slight expectoration; stools regular; urine normal, acid, 1028, no albumen; abdomen negative. Has not lost weight nor strength. Physical examination showed him well-developed and nourished. Tongue coated white. Lungs: good resonance throughout, except at the right apex behind, where it is somewhat dull, and where respiration is harsh and high-pitched; no râles.

January 10th. Dose, .0006 gm.

April 3d. Examination of the lungs (Dr. Mason). Percussion about the same on both sides. Right lung, front: harsh breathing at apex, but expiration not notably prolonged; fine subcrepitant râles throughout the front, especially between the second and third ribs; fine râles on cough. Left lung: normal. Behind: in right supra-scapular fossa, expiratory murmur slightly prolonged and harsh; very few fine râles, with cough; vocal resonance distinctly increased; faint bronchial whisper. The patient has had no hæmoptysis since entrance; no night sweats; no dyspnea. Good appetite; sleeps well. Slight congestion of hands. Has gained three pounds since entrance (169 to 172).

April 4th. Asks to go out.

Sputum: April 3d, 0; April 2d, 0; April 4th, 1.

April 11th. Haemoglobin test, 93%.

**Summary.**—Number of injections, 35; amount used, 287.6 mg.; highest dose, 10.8 mg.; highest temperature, 100.4°, after the twelfth injection of ten mg. Discharged relieved. General condition good. Slight, but constant gain in weight during treatment. Bacilli absent from sputum most of the time.

**CASE VIII.** Lives in Boston. Admitted January 10, 1891. Service of Dr. G. G. Tarbell. Born in Prince Edwards Island, forty-three years old, married, machinist. Mother had hæmorrhage of the lungs, and died at fifty-six years of age. One brother and two sisters died of phthisis. Was always well until last summer. General health is poor; had a hæmorrhage five months ago. Is well developed; pale; poor strength; somewhat emaciated; fair appetite; good sleep; heart and circulation negative; has had chills, fever and night sweats. Breathing is poor; coughs in the morning and evening; expectoration yellowish, and occasionally streaked with blood. Bacilli were found by Dr. Gannett. Slight pain. Urine high, acid, 1024, no albumen. Five months ago, after a hacking cough for some months, spit up three mouthfuls of bright red blood after exercise. Three or four similar attacks at that time, about thirty-six hours apart. Was weak, and stopped work. Severe night sweats, which stopped under treatment. Cough was persistent, chiefly in the morning and the evening, with yellowish sputum, occasionally streaked with blood. Appetite fair, but some loss of strength. Is stronger than last summer and able to do light work of late.

January 11th. Dose, .001 gm. Good sleep; increased pain in the left side; sputum watery.

April 9th. Signs in the chest about as before. General condition very good.

**Summary.**—Number of injections, 32; amount used 301.8 mg. Highest dose 14.4 mg. Highest temperature 101.4°, after the twenty-second injection, of twelve milligrammes.

April 29th. Diminished resonance; medium and fine moist râles over left front; right front normal; diminished resonance, and fine and medium moist râles over left back; right back normal. Weight 148½ pounds. Bacilli, No. 2. General condition good.

Discharged, not relieved. A gain of about five pounds during treatment. General condition about the same.

**CASE IX.** Waltham. Admitted January 21, 1891. Service of Dr. F. C. Shattuck. Born in Nova Scotia, thirty-two years old, married, type-setter. Sister died at twenty, of some lung trouble of short duration. Maternal grandmother and his maternal uncle and his children died of phthisis. Disease began six months ago with a cough and gastric disturbance; slight expectoration. General health good, except constipation. Lost about twenty-five pounds. Is of anemic appearance; fair strength; slightly emaciated; good appetite; sleep good, excepting when he coughs; slight accentuation of the second pulmonary heart sound; no night sweats, but a good deal of cough; slight expectoration; bacilli found in the sputum before entrance; some stinging and aching pains in the upper right chest; slight nausea; urine normal, acid, 1052, no albumen; abdomen negative.

Physical examination showed right upper and an-

terior portion less prominent than the left; infra- and supra-clavicular portions rather hollow. Sides move about equally in respiration. The lungs (right), at the apex, anterior and posterior, show slight dulness and broncho-vesicular respiration; anteriorly, scanty râles on breathing and cough, to the second rib; posteriorly, at the apex and along the para-spinal region, one-third of the way down the back, scanty, fine, moist râles; on the left, a few râles at the apex, front and back, with small limited area, with same signs as above; same in the anterior axillary line.

January 23d. Dose, .0005 gm. Poor sleep; nausea in the afternoon; quantity of expectoration diminished.

April 9th. Dose, .006 gm. Pain increased towards morning. Bacilli in the sputum, No. 3.

**Summary.**—Number of injections, 32; amount used 111.8 mg. Highest dose six mg. Highest temperature 101°, after the third injection of 3.2 mg.

April 29th. Rides a bicycle ten miles a day. Feels much better. Weight, 136 pounds. Physical examination shows slightly diminished resonance to third rib on right front; fine and medium moist râles after cough; increased vocal fremitus and bronchophony; left front normal; right back, few fine, moist râles about the middle of the scapula; left back normal. Could raise no sputum for examination.

Discharged, relieved. A gain in weight of about six pounds during treatment. Especially a gain in general condition.

**CASE X.** Boston. Admitted February 2, 1891. Service of Dr. A. N. Sumner. Born in England, sixteen years of age, school-girl. Lost one brother and sister of phthisis. Had influenza last winter. Disease began, following it, with cough. General health fair; fairly well developed; fair strength, nutrition, appetite and sleep; slight flushing of cheeks; heart tumultuous and rapid, otherwise negative; slight night sweats some time ago; temperature 98.1°; pulse 116; respiration 30; cough constant, increases in morning; expectoration not profuse, no blood; bacilli were found in the sputum; slight pain in the chest; tongue clean; abdomen negative.

Physical examination shows diminished respiration at the right apex, to the second rib. Respiration is not especially altered. Slightly increased vocal resonance; no râles heard. The remainder of the right front normal; left front negative, except harsh and prolonged expiration. The right back dull to the angle of the scapula; broncho-vesicular respiration and dry râles; vocal fremitus increased. At left back, area of dulness extends down to the left scapula; broncho-vesicular respiration; fine, dry, crackly râles.

February 4th. Dose, .0006 gm. Numerous bacilli in sputum. Weight 88 pounds.

March 10th. Tired all the time. Much headache; abdominal pains; cough not troublesome; small amount of expectoration. In the right front, slightly increased dulness; fine, dry râles also heard. Upper left front, signs distinctly, but not markedly increased since entrance. Both backs do not differ materially from entrance, but about the same. Sleep fair; appetite poor; strength slightly diminished.

**Summary.**—Number of injections, 8; amount used 11.2 mg. Largest dose 2.1 mg. Highest temperature 102.8°, after the third injection, of 1.8 mg. Discharged, not relieved.

**CASE XI.** Boston. Admitted January 14, 1891. Service of Dr. E. H. Bradford. Born in Maine, thirty

years old, married, printer. Family history good. Had severe sore throat four years ago, since then white and yellowish sputum at times. Fell on the knee in July, 1890. General health poor; lost from ten to fifteen pounds in weight. Of poor development, poor strength, nutrition and appetite; fair sleep; heart and circulation negative; night cough; white yellowish expectoration; bacilli found in the sputum; urine, acid, normal, 1026, no albumen; abdomen negative. His knee is now partly flexed; considerable swelling, especially on the inside, not conforming to the cavity of the joints. The patella does not float. There is great pain and sensitiveness. Plaster applied.

On February 8th, physical examination shows dullness over the left apex, and moist râles; increased vocal resonance, and diminished respiratory murmur over the whole left chest; the râles quite fine above, and medium and moderately coarse below.

February 7th. Bacilli, No. 1. Urine, pale, acid, 1020, no albumen.

February 8th. Dose, .0013 gm. Quantity of sputum increased.

April 14th. Dose, .006 gm. Patient never had any marked general reaction from the treatment, which was temporarily omitted to-day for the purposes of this paper.

*Summary.*—Number of injections, 27; amount used 171.9 mg. Highest dose 10 mg. Highest temperature was 101°, after the fourth injection, of 7.2 mg. Discharged, much relieved.

May 5th. Sputum examinations showed a very marked diminution in the number of the bacilli. The knee not much improved.

CASE XII. Boston. Admitted February 25, 1891. Service of Dr. T. M. Rotch. Born in Russia, forty-five years old, married, shoemaker. Family history negative, former history good. Commenced three years ago with a cough. Been hoarse for nine months. Showed loss of strength and flesh for the last year. Nutrition fair; fair appetite; heart and circulation negative; night sweats; temperature 99°; pulse 96; respiration 28; troubled with dyspnea; cough worse in the morning; slight increase in expectoration; pain in the left chest and back; stools and abdomen negative. Examination showed lips to be cyanotic; the voice hoarse; color good; tongue moist and white; respiration quiet; pulse of good strength and regular. Lungs at both apices show slight dullness, diminishing to the second rib, and a few fine, moist râles; no bronchial breathing; below, respiration is somewhat harsh; back shows a few moist râles in upper left side.

February 28th. Seemed to have been helped by respirator. Several muco-purulent expectorations daily. Pain in the left side.

March 2d. Bacilli on March 1st, No. 6. Weight 128 pounds. Hemoglobin, 75 per cent.

March 3d. Urine, normal, clear, 1018, albumen showed very slight trace; leucocytes and bladder cells.

March 6th. Dose, .0008 gm.

April 14th. .008 gm.

*Summary.*—Number of injections, 18; amount used 63.1 mg. Highest dose .0018. Highest temperature 100°, the second day after injection No. 15, of .0018 gm. Discharged, relieved. Bacilli disappeared very markedly from the sputum.

Of these cases, most were of from six months to five years standing. The two, in which the history extended

for shorter time than this, were Case 5, in which the bacilli were never found, and Case 7, in which there was a record of a cough for only two months. Case 5 may possibly have been one of specific disease, and Case 7 is classified as improved, as will be seen later.

The general summary of the results, as seen in these cases, is as follows:

(1) Not relieved, seven, including Cases 1, 2, 3, 5, (in which the bacilli were never found), 6, 8 and 10. Case 2 was one with the complication of laryngeal and probably abdominal trouble.

(2) Relieved, five, including Cases 4, 7, 9, 11 and 12.

Case 4, (complicated with marked lesions of the skin in the cervical region), is classed as relieved, because of the marked diminution of the bacilli in the sputum, the great gain in weight, and the marked improvement in the general condition. The skin lesions made an improvement for a time, but then stopped, and were no better at the time that the treatment was omitted.

Case 7 is marked relieved, for the reason that the patient showed a slight but constant gain in weight; the bacilli were absent from the sputum most of the time; the general condition was extremely good; and the patient asked to be allowed to go out in order to go to work.

Case 9 is classed as relieved, because of the gradual gain in weight during treatment, and the marked improvement in the general condition, as shown by the patient's ability to take severe exercise without fatigue or pain.

Case 11 (pulmonary tuberculosis complicated with an affection of the knee) is classed as relieved, for the reason that the bacilli showed a very marked and permanent diminution in the sputum, and the signs attracting attention to the chest had much diminished. The knee was not improved.

Case 12 (complicated with laryngeal affection) is classed as improved, for the reason that the bacilli have shown a marked and continuous diminution in the sputum, the laryngeal appearances have cleared up somewhat, and the general condition is improved, with a gain of six pounds in weight.

There were no cases in this class that could be called cured, and no deaths.

(To be continued.)

## A SECOND SERIES OF TWO HUNDRED CONSECUTIVE CASES OF MIDWIFERY.<sup>1</sup>

APRIL 11, 1888, TO MARCH 9, 1891.

BY A. WORCESTER, A.M., M.D., WALTHAM, MASS.

ONLY ninety-seven, less than fifty per cent. of these cases are classed as normal as regards both the labor and the convalescence. But, as in thirteen of the cases the birth of the child took place before my arrival, in only four of which was there any trouble; and as in eleven other cases I was called in consultation especially to operate, the proportion of absolutely normal cases occurring in my practice is really fifty-five per cent.

In studying the records of these normal cases, it is difficult to determine and still more difficult to com-

<sup>1</sup> Read by invitation before the Obstetrical Society of Boston, April 11, 1891. The first series of two hundred cases was reported by Dr. Worcester in the Boston Medical and Surgical Journal, vol. cxxi, p. 427.

municate the particular advantages, which nevertheless are obtainable only by such study. The ability to decide whether or no a labor is normal in its conditions and progress is of immense advantage, not only in selecting the most favorable time for interference if that be necessary, but even more in stimulating the patient to renewed exertions by making her confident of her labor's happy termination.

Such ability grows out of closest study of the normal as well as of the abnormal cases. I therefore include in this report the dry facts concerning the normal as well as the more interesting data of the abnormal cases.

Seventy-four, or 37 per cent., were i-iparae, whose average age was twenty-four and a half years; 46, or 23 per cent., were ii-iparae, average age twenty-eight; 25, or 12½ per cent., were iii-iparae, average age twenty-nine and a half; 18, or nine per cent., were iv-iparae, average age thirty-one and a half; nine, or four and a half per cent., were v-iparae, average age thirty and a half; nine, or four and a half per cent., were vi-iparae, average age thirty-three; eight, or four per cent., were vii-iparae, average age thirty-four; three, or one and a half per cent., were viii-iparae, average age thirty-nine; four, or two per cent., were ix-iparae, average age thirty-six; two, or one per cent., were x-iparae, average age thirty-four; one, or one-half per cent., was a xii-iparae, aged thirty-eight; and in one, or one-half per cent., these facts were not noted.

The average duration of the first stage in 51 i-iparae was 12 h. 30 m., the longest being 56 h., the shortest 3 h.; the average of 33 i-iparae in the second stage was 2 h. 30 m., the longest being 4 h. 30 m., the shortest 35 m.

In 39 ii-iparae the average duration of first stage was 5 h. 36 m., longest 17 h. 45 m., shortest 30 m.; second stage in 36 cases, average 1 h. 20 m., longest 10 h., shortest 15 m.

In 17 iii-iparae average duration of first stage 7 h. 40 m., longest 17 h., shortest 2 h.; second stage, 17 cases, average 40 m., longest 1 h. 20 m., shortest 15 m.

In nine iv-iparae average duration of first stage 7 h. 10 m., longest 12 h., shortest 1 h.; in second stage, nine cases, average 45 m., longest 1 h., shortest 20 m.

In six v-iparae average duration first stage 8 h. 5 m., longest 17 h., shortest 2 h.; second stage, five cases, average 56 m., longest 1 h. 30 m., shortest 20 m.

In 21 women who had borne more than five children the average duration of the first stage was 5 h. 55 m., longest 14 h. 30 m., shortest 2 h.; second stage, 18 cases, average 44 m., longest 1 h. 30 m., shortest 15 m. Of 113 cases the average duration of the third stage was 12 m., the longest 30 m., the shortest 5 m. It is proper to state in this connection that almost never have I left the uterus unaided in the third stage of labor, my practice being to hold the fundus firmly throughout this stage, and to press downwards and backwards at the times of uterine contraction.

As regards the position of the fetus, out of 155 cases where noted, O. L. A. occurred 111 times, or 71½ per cent.; O. R. P. 22 times, or 14½ per cent.; O. R. A. 18 times, or 11½ per cent.; O. L. P. twice, or 1½ per cent.; S. R. P. twice, or 1½ per cent. Thus in 129 cases, 83½ per cent., the occiput was anterior. In 26 cases, 16½ per cent., it was posterior; in 10 of

these cases of posterior position, 39 per cent., operative aid was required; while in 129 cases of anterior position only 22, or 17 per cent., went to operation.

As affecting the duration of labor, in five cases of posterior position in i-iparae the average duration of the first stage was 17 h. 18 m., of the second, 2 h. 52 m.; while in 30 cases of anterior position in i-iparae the average duration of the first stage was 12 h. 9 m., and of the second 2 h. 2 m.

Of the thirteen cases where the child was born before my arrival, in two there were slight lacerations, and in two more there were serious lacerations of the perineum. In none of these cases was there any hemorrhage. Only one child was stillborn and that was a macerated syphilitic.

Sixteen of the two hundred pregnancies terminated before full term. Nine of these were abortions proper; in one case the entire fetal mass was expelled, but in eight cases there being doubt as to the entirety of the expelled mass, I curetted and douched the uterus with bichloride solution (1 to 8000). In three of the five cases of miscarriage, I also curetted and douched the uterus. Recoveries in all these cases were uninterrupted. Of the two cases of premature birth, one child born at seven months died in a few hours, one born at eight months lived.

In 41 cases operative assistance was given. After deducting the eleven cases where I was summoned purposely to operate, it will be found that 16 per cent. of my patients were operated upon. Although reduced from 18 per cent. for my first series of two hundred cases,<sup>2</sup> this is still a large proportion. And either my class of patients differs from that of other practitioners who are able to report only exceptionally finding operative cases, or else I operate too readily.

As to the cases where even with axis traction the delivery was hard, there can be, I suppose, little question of the necessity of the operation. The question becomes more plausible in considering the ten cases where forceps were applied to the head arrested in the inferior straits. In two of these latter cases extraction was difficult; in one there was the impediment of an ankylosed coccyx bent inwards at a right angle, in consequence of an injury; in another there was an exostosis of the left tuberosity of the ischium. In the six remaining cases where low forceps was used and where the extraction was easy, the reasons for operating were that the labors were not progressing and the patients were showing signs of exhaustion. In several of these cases, perhaps in all, natural delivery would probably have occurred in time. And the question of the propriety of operating depends upon balancing the grave dangers of exhaustion and the slight dangers of the operation. As a matter of fact there was a slight post-partum hemorrhage in one of these six cases, and a slight laceration of the perineum in three others; while in 115 normal cases there were only 26, or 18½ per cent., in which laceration occurred, and post-partum hemorrhage occurred in 15, or in 10 per cent.

Of the four mothers who died, as is shown in the following reports, not one died from the effects of operation. But of the twelve stillborn children, two deaths were due to craniotomy, performed after the accidental crushing of the skull in attempts to deliver with forceps; in two more cases death was undoubtedly due to the instruments; in three cases the fetus

<sup>2</sup> Boston Medical and Surgical Journal, May 2, 1889.

TABLE OF EIGHT PODALIC VERSIONS.

No.	Para.	Pos. and Pres.	Reasons for Operating.	Character of Operation.	Anæsthetic	Weight and Condition.	Damages.
1	V	O. R. A.	Patient exhausted after nine hours of 2d stage labor.	Clumsy. Much trouble in bringing down arms.	Ether.	Seven pounds. Easily resuscitated.	None.
2	VIII	O. R. P.	Narrowed conjugate. No progress. Called in to operate.	Extremely difficult.	Ether.	Ten pounds. With difficulty resuscitated. Partially paralyzed. Died in one year.	None.
3	III	O. R. A.	Prolapsed cord. Called in to operate. "Forceps" had been tried for hours.	Difficult, because of contracted uterus.	Ether.	Thirteen and one-half pounds. No heart-beat, though good color, under artificial respiration for one hour.	Moderate laceration of perineum.
4	VI	Head.	Placenta-prævia. Considerable hæmorrhage.	After manual dilatation, easy.	Ether.	Six pounds.	None.
5	II	Head.	Placenta-prævia centralis. Called in to operate.	Difficulty in delivering head.	Ether.	Hydrocephalic. Spina-bifida. Still-born.	Perineum lacerated half-way. Died from hæmorrhage.
6	IV	O. R. P.	Contracted pelvis. No pulsation in cord.	Very difficult.	Ether.	Ten pounds. Still-born.	Laceration of the perineum.
7	I	Head.	Phthisical patient. Was exhausted.	Easy.	Ether.	Five pounds.	Post-partum hæmorrhage.
8	II	Head.	Eclampsia. Called in to operate.	Manual dilatation.	Ether.	Six months' fetus, dead.	Died sixth day.

had been dead for some time previous to the labor; three more are reported in the table of Versions; and the remaining two were in cases of breech presentation where there was no pulsation in the cord at the time of its delivery.

Of the four babies who died within ten days of birth, one was a hæmophilia, one died from marasmus, and two died from the effects of instrumental delivery.

So far as the cases of this series are concerned the advantages and disadvantages of employing high forceps or podalic version are shown only in the reports of the infant mortality.

Before we had axis traction instruments, and before I found out that it is perfectly practicable in applying high forceps to rotate the head into the most favorable position, and to hold it there while applying the instruments, I believed that the employment of version offered a better chance of life to the fetus. I knew that the mother's perineum was more endangered. I now believe that there is an advantage on the side of high forceps as regards both mother and child.

#### CASE I. Pulmonary embolism; death.

Mrs. E. F., primipara, twenty-four years old, a strong, vigorous woman, was taken in labor at midnight February 3, 1889. The first stage ended at 9 p.m. the next day. After two hours, the pains slackened. There was no engagement of the breech, which was in left anterior position. Ineffectual attempts were made with fingers hooked in groin to draw down the breech.

At 12 a.m., February 4th, with Dr. H. A. Wood's assistance the patient was etherized. As soon as she became fully anesthetized, while in operative position, she vomited a thin, darkish fluid, and immediately became cyanosed. She was at once turned upon her side, her tongue held forward, and every effort made to assist the violent coughing that ensued. I supposed that she had inspired some of the vomitus; but I now believe that a pulmonary embolism occurred at the time of vomiting.

After an hour's interval she was again etherized. With Dr. E. R. Cutler's assistance, and by means of the blunt hook, the left, and finally the right leg, was delivered. The pelvis was evidently abnormally small, and only by tremendous traction was the child, a boy of eight pounds, delivered. There was no heart beat. The mother's perineum was torn to the sphincter ani. She was still cyanosed. Her pulse was 140. As she came out of the ether the dyspnoea increased. Heart sounds obscured by the sonorous explosive rales. Digitalis and carbonate of ammonia were given subcutaneously. She rallied somewhat, and for several hours was able to talk, but was still cyanotic. Died at noon.

#### CASE II. Septicæmia; death.

On February 28, 1890, Mrs. T. R., a primipara, twenty-three years old, had been in labor sixty hours. I hastened the delivery of an eight-pound girl by completing the dilatation of the os, and by rotating the occiput from the right posterior position to the front. All went well till the morning of the fifth day, when she had a chill, and became delirious. Her old nurse had let the bed become filthy. After cleaning her surroundings, I douched and thoroughly curetted the inside of the uterus, and inserted an iodoform pencil. There was no improvement. General peritonitis followed, and she died on the seventeenth day.

I ought to have made an abdominal section, and cleared out the infected area. The case was complicated by a mitral insufficiency, and by general family rows, owing to the discovery that her marriage was only a pretence.

#### CASE III. Placenta-prævia centralis; death.

Mrs. F. G., secundipara, eight months' pregnant, had been flowing freely for twelve hours, when I was called in consultation, February 14, 1890. Her strength was good, her pulse fairly full. She was having occasional pains. The os was half dilated, and the placenta firmly attached all round. Under full anaesthesia I dilated the os manually, bored through the placenta, and did podalic version. With considerable difficulty I delivered her of a dead fetus (spina

bilida and hydrocephalus). Neither during nor after delivery was there excessive hemorrhage. The placenta came away easily. The ruptured perineum was repaired. But in spite of intrauterine douches of hot water and of vinegar, of ergot given by the mouth and subcutaneously, the uterus did not contract well, and some flowing continued till her death five hours after delivery.

CASE IV. Adherent placenta; post-partum hemorrhage; septicæmia; recovery.

Mrs. W. J., a secundipara, thirty-four years old, after passing easily the second stage of labor, began flowing frightfully. On attempting to extract the placenta I found it firmly adherent in the left lower segment of the uterus. I dug it out as best I could, curetting vigorously and using hot douches of 1 to 8000 bichloride solution. She became pulseless, but rallied well. On the third day she had a chill, and, for six days afterwards, evident septicæmia. Intrauterine douches of bichloride solution (1 to 8000) were given for three days. A sharp diarrhœa followed; and then rapid convalescence.

CASE V. Eclampsia; induced labor; death.

I was called in consultation January 6, 1891, to see Mrs. S., a strong woman of forty-eight years, who was then comatose. She had been pregnant once, nine years before, but had miscarried at three months. She last menstruated June 11, 1890. Five months afterwards she felt fetal motion. Beyond feeling more tired than usual and being very constipated, she had been well till within the last few weeks. She had, during this time, suffered from headache for the first time in her life.

The day before she was as well as usual till night, when she was seized with "cramp colic." At 3 A. M. January 6th, six hours before my first visit, she had had a convulsion.

Her urine, drawn by catheter, solidified on boiling. I immediately dilated the os uteri, first with a uterine sound, then with Ellinger dilators, and lastly with my fingers—one of which did not recover from numbness for two months. By podalic version the dead fetus was delivered.

The patient rallied well, becoming fully conscious the next day. But her urine grew scantier, and she died on the fifth day.

CASE VI. Contracted pelvis.

On February 1, 1889, I was called in consultation to deliver Mrs. C., a stout woman, twenty-six years old. This was her third pregnancy. The first resulted in a craniotomy; the second in a still-birth by podalic version. She had been in the second stage of labor for many hours, and forceps had been several times tried. I found the head presenting in right posterior position, not engaged. After rotating the occiput to the front I applied forceps and the Reynolds traction-rods. The extraction was difficult. The boy baby weighed eight pounds. There was no heart beat, and all efforts to resuscitate failed. The mother made a good recovery, and the next year applied to me to take charge of her in her fourth confinement.

I made these measurements: Distance between the anterior superior spinous processes, 7 in.; between the iliac crests,  $9\frac{1}{2}$  in.; between the tuberosities of the ischia,  $3\frac{1}{2}$  in.; the external conjugate, 7 in.; the diagonal conjugate,  $4\frac{1}{2}$  in.

She was taken in labor August 8, 1890. After twelve hours, the os being nearly dilated and the pains

amounting to nothing, I completed the dilatation, rotated the occiput from the right posterior to front position, applied forceps and traction-rods. On vigorous pulling I broke the left frontal bone, just above the zygomatic arch. I then performed craniotomy, and with difficulty delivered a female child which, minus brains and blood, weighed eight pounds. There was a severe post-partum hemorrhage, finally controlled by hot intrauterine douches of one per cent. acetic acid. The patient made a good recovery and is again pregnant.

CASE VII. Contracted pelvis.

Distance between anterior superior spines,  $8\frac{1}{2}$  in.; between crests of ilium, 9 in.; between trochanters, 11 in.; external conjugate, 6 in.

On February 15, 1889, I was called in consultation to deliver Mrs. W., a small, sickly primipara, twenty-five years old. She had been in labor two weeks. The membranes had protruded and broken, and were putrid. She had had hard pains for two days previous, but was having none at the time of my visit. She was not able to retain any nourishment.

I found the os uteri nearly dilated, the head presenting in left anterior position. There was a very prominent caput succedaneum, but the head was not engaged. The uterus was firmly contracted. Forceps was applied with difficulty on account of the tightness of the vagina. With axis traction-rods, after an hour of hard pulling, I delivered a nine-pound boy, who lived only four hours.

The head, during its passage through the pelvis, became jammed into the right side. The forceps was not well applied, for one blade tore the scalp over the right frontal bone. The perineum was lacerated to the sphincter ani, and there was considerable post-partum hemorrhage.

Her convalescence was uninterrupted.

CASE VIII. Contracted pelvis.

Distance between anterior superior spines,  $7\frac{1}{2}$  in.; between crests of ilium, 9 in.; between trochanters,  $10\frac{1}{2}$  in.; external conjugate,  $6\frac{1}{2}$  in.

Mrs. O. S., primipara, twenty-one years old. First pains, July 23, 1889, all day. Then comfortable till July 30th, when she had pains for a few hours; no sleep that night. July 31st, pains very infrequent; slept well. August 1st, 2 P. M., pains began hard, and waters came; no further dilatation at 9 P. M. Chloral given with no effect, except to ease her. Cervix lips wire-edged; excruciating suffering; but no dilatation. At 9 P. M., full anaesthesia and manual dilatation. O. R. P. At 1 A. M., pains not engaging head, I put on forceps and traction-rods, under mistaken impression that I had rotated occiput to front. Very hard extraction—of face under arch. Difficult resuscitation. Boy, seven pounds. Perineum lacerated half way to the sphincter ani. Convalescence normal.

CASE IX. Contracted pelvis.

Distance between anterior superior spines, 10 in.; between crests of ilium, 11 in.; between trochanters, 13 in.; external conjugate, 8 in.

Mrs. P. C., quadripara. Labor began at 8 P. M., May 17, 1890. At midnight I found os dilated. For two hours pains hard, but no engagement. I ruptured membranes, but no gain. With Dr. H. A. Wood's help etherized, and tried manually to rotate O. R. P. to anterior position. This failing, and finding no pulsation in cord, I did podalic version. But after deliv-

ering body and arms, I was obliged to have Dr. Wood deliver head. Boy, ten pounds, still-born. Laceration of the already poor perineum. Convalescence normal.

#### CASE X. Contracted pelvis.

Distance between anterior superior spines,  $7\frac{1}{2}$  in.; between crests of ilium,  $10\frac{1}{2}$  in.; between trochanters,  $12\frac{1}{2}$  in.; external conjugate,  $6\frac{1}{4}$  in.

Mrs. L. R., primipara, twenty-five years old. I was called to operate at 5 p. m., December 27, 1890. She had been in labor twenty-four hours, but was then having only worthless pains. Under anesthesia I completed the dilatation of the os uteri, rotated the occiput from the left posterior position to the front, and applied forceps and the axis traction-rods. After tremendous pulling I delivered an eight-pound boy, who died on the day following from effects of the instruments. I doubt not. One eye-lid was torn. The mother did well.

### LAPAROTOMY, VERIFYING THE DIAGNOSIS OF PELVIC CELLULITIS.<sup>1</sup>

BY CHARLES P. STRONG, M.D.

So thoroughly is the idea now established among the profession that collections of pus in the pelvic cavity are the result of inflammatory action set up by tubal disease, that the condition formerly called, and treated as, cellulitis, or inflammation of the cellular tissue, in various parts of the pelvis, is practically disregarded. In consequence, instead of aspiration followed by drainage, the tendency is to treat all cases by laparotomy, with the idea of removing the offending tubes.

The following case in which the diagnosis was verified by subsequent laparotomy, is, in this connection, one of very great value.

Miss K., had been a sufferer all her menstrual life with pain at the menstrual period, and inability to walk or stand at that time. She had been bed-ridden for several months at a time with attacks of pelvic inflammation.

In the summer of 1890, one of these attacks left behind it a collection of pus, which was evacuated through the vagina. At that time it was considered that, although this abscess was opened, drained and healed, still there was left behind the cause of the purulent collection, namely, salpingitis.

I first saw the patient in December, 1890, at which time she was just recovering from a severe attack of gastritis. With her menstrual history, and the fact that she was obliged to support herself; having in view the fact that she had had these repeated attacks of inflammation; having in view, also, the fact that the exhaustion consequent upon the suffering during each menstrual period was so extreme that she could not rally her strength before the catamenia again appeared,—with the full consent, or rather, at the urgent request of the patient, I performed laparotomy in December, removing the tubes and ovaries of each side.

I found both ovaries and tubes, in gross appearance, healthy. There was no indication of any salpingitis, either pre-existent or then existent; nor could anywhere in the pelvis be detected the signs of any of the previous attacks of so-called pelvic peritonitis, except the existence of a few fine bands of adhesion holding

down the ovaries, which were displaced posterior to the uterus in Douglas's fossa.

The only evidence of the disease of last summer was to be found in a slight thickening of the cellular tissue between the peritoneum, which dipped down into the retro-uterine space, and the posterior cul-de-sac of the vagina. This thickening was entirely subperitoneal.

It would seem, therefore, beyond all question, that the abscess which last summer was opened, drained and healed, and, very probably, these attacks, or many of them at least, which had been called pelvic peritonitis, had their origin, not in the pelvic peritoneum, but in the cellular tissue investing that membrane; that is, this had been a case of true pelvic cellulitis.

While entirely in accord with the majority of the profession, who do thus thoroughly believe in the tubular origin of pelvic inflammation, I yet feel that the evidences of this case demand a suspension of our judgment in too hastily condemning those who are inclined to adopt, in many cases, the more conservative measures of opening an abscess that can be easily reached through the vagina, and draining through that canal, unless strong evidences have been presented of previous tubal disease.

Furthermore, in this case, there was doubly a reason to anticipate tubal disease, from the fact that the patient had for many years been the subject of endometritic and endocervical inflammation.

NOTE.—June 1, 1891. Since the operation, six months ago, the patient has not menstruated; has gained very much in general health and freedom from pelvic disturbance of pain and discomfort. Her only complaint now is leucorrhœa from endometritis, for which I have advised curing.

## Medical Progress.

### RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M.D.

#### TOXIC ACTION OF URANIUM SALTS.

WOROSCHILSKY's<sup>1</sup> experiments confirm the statement, first made by Leconte, in 1851, and more recently by Chittenden, that glycosuria is a constant and characteristic symptom in poisoning by the salts of uranium. As a result of eight experiments with the nitrate, he agrees with the conclusion of Leconte and Chittenden that it is intensely poisonous. But neither the nitrate or the acetate is well suited for physiological investigations, as both salts coagulate albumen, even when diluted in the proportion of 1:10000. Further experiments were, therefore, instituted with the double tartrate of uranium and sodium, which is readily soluble, and does not precipitate albumen.

The physiological action of this salt, exhibited in various ways, was studied in the case of worms, frogs, birds, and mammals. It was found that whether absorbed through the mucous membrane of the stomach, or introduced by subcutaneous injection, it is powerfully poisonous. Subcutaneous doses of 0.5–2.0 milligrammes per kilogramme of body weight cause death with all the symptoms of acute poisoning. It is noteworthy that very small doses administered subcutaneously are almost as quickly fatal as are considerably larger quantities, the only difference being that the action of the latter on the organs affected is more marked. It is remarkable that during the first day or

<sup>1</sup> Read before the Obstetrical Society of Boston, April 1, 1891.

<sup>1</sup> American Journal of Pharmacy, January, 1891, p. 22.

two after the administration of the poison there is no outward evidence of its effects save the pathological character of the urine, although afterwards the toxic action is increasingly manifest.

The symptoms produced by poisonous doses of uranium salts are as follows: severe gastro-enteritis follows its administration, while nephritis is induced by such small doses as one to two milligrammes per kilogramme of body weight. It is distinguished from other metallic poisons by acting directly, even in small doses, on the walls of the blood-vessels. This tendency is doubtless closely connected with its specific action on the blood, by causing the hæmoglobin to retain oxygen altogether abnormally, in which respect it resembles hydrocyanic acid.

When the uranium salt is introduced into the circulation, the oxyhæmoglobin, which is, from the action just mentioned, reducible only with difficulty, probably affects the walls of the blood-vessels in the same manner as venous blood, and causes their dilatation. The failure of the oxyhæmoglobin, under the influence of the uranium salts, to part normally with its oxygen accounts also for the profound disorganization of the nutritive functions which ensues, and for the derangement of the nervous system, liver and kidneys, which accompanies it. It also explains the general waste of tissue, resulting in the emaciation of the animal under experiment, which was a characteristic symptom, and further affords an explanation of the appearance of sugar in the urine; which is merely a sign of imperfect oxidation in the circulatory system, disappearing with the removal of the ultimate cause.

#### POISONING BY BARIUM CHLORIDE.

Acute poisoning by the salts of barium is of rare occurrence. The following case, reported by MM. Ogier and Socquet,<sup>2</sup> is therefore of special interest. About twenty grammes of the salt were taken by mistake for magnesium sulphate. Almost immediately violent vomiting ensued, followed soon after by diarrhoea. The vomitus was at first greenish in color, later bloody. Death occurred in five hours.

At the autopsy the following conditions were found: there was slight congestion of the lungs. The mucous membrane of the stomach was very much swollen, and red in places owing to ecchymoses. The kidneys were congested. The cavities of the heart contained a small amount of blood, a part coagulated, a part fluid, somewhat viscid, and dark in color. The intestines contained a small quantity of fluid contents; the mucous membrane was normal. The brain and meninges did not present the "congested" character which has been noted in certain cases of poisoning by the salts of barium.

The authors made a separate determination, with the various organs, of the unchanged barium chloride, and the barium chloride which had been changed to sulphate by the action of the sulphates in the system. No barium chloride was found in the contents of the stomach or intestines. The liver contained 0.126 gramme of hydrated barium chloride; kidneys, 0.050 gr.; lungs, 0.070 gr.; 15 grammes of blood taken from the heart, 0.003 gr.; spleen, a trace too small to estimate; brain, none.

The distribution of the barium sulphate was as follows: contents of the stomach, a trace; contents of

intestines, 0.019 gr.; liver, 0.088 gr.; kidneys, 0.028 gr.; spleen, 0.003 gr.; lungs, 0.021 gr.; blood from heart, 0.003 gr.; brain, none. There was thus an entire absence of unchanged barium chloride in the contents of the stomach and intestines; these containing barium sulphate only, and of that a mere trace. The blood and various organs of the body contained both chloride and sulphate.

The great disproportion which exists between the quantity taken and the quantity isolated from the organs is noticeable. While twenty grammes were taken, less than one-half gramme was recovered. The explanation is to be found in the prompt removal of the poison by vomiting. The salts of barium apparently resemble in this respect, the salts of certain other metals, for example, copper. There is no relationship between the quantity ingested, and the quantity fixed in the tissues. Apparently, nearly as much may be absorbed from the administration of small non-poisonous doses as from the ingestion of a large quantity. The recovery, therefore, of a small quantity from the organs, does not justify the conclusion that the quantity taken was small and incapable of causing death.

The authors call attention to the fact that, although the isolation and identification of the salts of barium present no difficulties, their presence may be very easily overlooked, unless attention has been directed to them by the history of the case.

The authors, as a result of numerous investigations, reject the hypothesis which has been suggested, namely, that the salts of barium determine death as a result of their conversion into sulphate thus forming a mechanical obstacle to the circulation.

#### STRONTIUM SALTS.

In a paper read before the *Société de Biologie*, Professor Laborde<sup>3</sup> stated that the salts of strontium are harmless, even when given for relatively long periods of time. They produce diuretic effects, however, and these have been substantiated, clinically, by Professor Sée, who used the lactate and the tartrate of strontium. They thus differ from barium salts, which are very toxic. Dr. Laborde thought that the strontium salts exercised a preservative action upon organic tissues, liquids and excretions.

#### MERCURY.

Observations made by Marco T. Lecco<sup>4</sup> during the examination of a human stomach containing mercury, show that this metal is not readily soluble in hydrochloric acid on the addition of potassium chlorate; and that, therefore, in the destruction of organic substances containing mercury, by means of these reagents, the entire quantity of mercury present passes into solution only with difficulty. In the stomach in question minute metallic globules could be distinctly seen, which, when separated, were recognized with certainty as mercury.

In order to test the stomach for other mineral poisons and to determine the mercury, it was exposed to the action of hydrochloric acid and potassium chlorate. After the destruction of the organic matter, the product of the reaction was worked up in the ordinary manner. But on examining the solution it was scarcely possible to find the slightest trace of mercury. In consequence, the undissolved residue was examined

<sup>2</sup> Annales D' Hygiène Publique et de Médecine Légale, May, 1891, p. 417.

<sup>3</sup> American Journal of Pharmacy, March, 1891, p. 129.

<sup>4</sup> Chemical News, May 29, 1891, p. 251, from Berichte der Deutsch. Chem. Gesellschaft, xxi, No. 6, p. 728.

more closely, and found to still contain mercury. Further experiments were conducted with pure mercury, in which the action of concentrated and dilute acid, at common temperatures, with prolonged action and on the water bath was tested, and in all cases the result was that mercury is with difficulty soluble in the reagents named. It is, therefore, absolutely necessary in the destruction of organic matter by this process to keep this property of mercury in mind, and to prolong the action of the acid and the chlorate for some hours, with the application of heat and with frequent stirring.

#### DETECTION OF COLCHICINE.

N. Obolonski<sup>6</sup> recommends the following process: The finely divided viscera are rubbed up with glass powder, treated with oxalic acid, and digested for twelve hours with alcohol. The liquid is squeezed out, and the dry residue twice washed with alcohol. The extract is concentrated at a temperature not exceeding 80°, and the cooled residue made up to the original volume with alcohol. The filtered liquid is evaporated as before, and this operation repeated until no clots separate on the addition of alcohol. The residue is then dissolved in water, the solution purified by shaking with light petroleum, and the colchicine finally extracted with chloroform as usual.

The alkaloid is best identified by means of the violet color produced by nitric acid; by Erdmann's reagent (nitro-sulphuric acid), which gives in succession green, dark blue, violet and yellow colors, turning to raspberry red on adding alkali; also by Mandelin's reagent (one gramme of ammonium vanadate in 200 grammes of sulphuric acid), which gives a green color. Colchicine is with difficulty destroyed by putrefaction of animal matter. The kidneys, bladder and urine are best suited for forensic examination.

#### SUGAR.

Hunkiarbeyendrian<sup>7</sup> adds salol to the list of substances which impart to urine the property of reducing the oxides of copper, silver and bismuth in alkaline solution. The urine of persons to whom salol has been administered, furnishes, when tested with Fehling's solution, a precipitate of the red oxide of copper, the quantity varying with the amount of salol absorbed. If such urines contain at the same time sugar, the polariscopic test is also subject to error, since urines containing derivatives of salol polarize to the left; the results obtained are therefore too low.

To distinguish in urine, sugar from the derivatives of salol, the following process is recommended: A tube of the capacity of fifteen cubic centimetres, is half filled with urine previously treated with basic acetate of lead. To this is added five centigrammes of hydrochlorate of phenyl-hydrazin and twenty centigrammes of sodium acetate. The liquid, which assumes a yellow color, is heated in the water-bath to 100° for half an hour, and then allowed to cool, when the precipitate formed is examined microscopically. If due to derivatives of salol, the precipitate is amorphous; if to sugar, it is composed of small, silky crystals of phenyl-glucosazone, which are at times grouped into tufts.

A more rapid process, which does not require the employment of the microscope, is the following: To 200 cubic centimetres of urine, there is added one gramme of sulphuric acid and about 50 cubic centi-

metres of ether free from alcohol. The mixture is shaken for several minutes, then allowed to stand awhile. The upper layer, which contains the derivatives of salol, is evaporated in a porcelain capsule, the residue thus obtained dissolved in a little water, and the solution tested with a few drops of a solution of the perchloride or persulphate of iron. A violet coloration is produced in the presence of derivatives of salol. The lower layer of liquid is treated with basic acetate of lead, and, after filtration, tested for sugar by the ordinary methods. Non-saccharine urines containing derivatives of salol, when treated in this manner, have no action on metallic oxides, or on the rays of polarized light.

Jolles<sup>7</sup> considers that a sharp distinction exists between glycolic and diabetic urines. The former contain but mere traces of sugar, about 0.4-0.5 per cent., and otherwise are not characterized by abnormal chemical and physical properties. The diabetic urines, on the other hand, have a high density, a pale-yellow color, a less quantity of uric acid than normal urine, and contain acetone, or aceto-acetic acid, or acetic acid. Sugar usually occurs in them in considerable quantities, although this is not always the case. A new method, namely, to paint a visiting card first with copper sulphate solution, and, after drying, to apply the suspected urine with a match, dry and heat, which has recently been proposed by v. Becker, is considered wholly untrustworthy by the author. Trommer's method, and Seegen's modification of the same, are also considered valueless by the author. Böttger's bismuth reagent and the phenyl-hydrazine test are found by him to be trustworthy. With Böttger's bismuth reagent, 0.08 per cent. of sugar may be detected, and if the urine be first boiled with a solution of sodium chloride the delicacy is heightened, 0.01 per cent. being then detectable. At least fifty cubic centimetres of urine must be employed to five cubic centimetres of Nylander's reagent, and should not be boiled for more than two minutes. The presence of such substances as rhubarb, kairine, oil of turpentine, quinine, arsenious and salicylic acids, sulphur, mercury salts and iodides, should be avoided. In the case of considerable quantities of uric acid, it is to be observed that the brown coloration produced by it remains constant, whereas that produced by the presence of sugar becomes continually darker. The phenyl-hydrazine test enables 0.015-0.038 per cent. of sugar to be detected, the delicacy being the greater, the less the amount of reducible substances present. At the same time crystals, very similar to those of phenyl-glucosazone, are formed with glyceronic acid. The latter are, however, not so fine, and have not the same striated arrangement as those of phenyl-glucosazone.

Hirsch<sup>8</sup> considers the phenyl-hydrazine test a perfectly trustworthy one. If the urine gives typical needles of phenyl-glucosazone, it certainly contains glucose. It is essential, however, that the test-tube should be allowed to remain one hour in the water-bath. If this is done, the precipitate caused by glyceronic acid, if this substance is present, is wholly amorphous, and easily distinguishable from phenyl-glucosazone. Levulose cannot be distinguished from dextrose by this test, but only by the polarimeter. Lactose, which has been found in the urine of nursing women,

<sup>6</sup> Journal of the Chemical Society, London, Jan., 1891, p. 135.

<sup>7</sup> Journal de Pharmacie et de Chimie, Nov., 1890, p. 124.

<sup>7</sup> Journal of the Chemical Society, London, March, 1891, p. 369.

<sup>8</sup> Journal of the Chemical Society, London, July, 1890, p. 836.

furnishes needle-shaped crystals, which are about ten times the width of those of phenyl-glucosazone, and do not show the same orderly arrangement. Their melting point is 200°. Maltose gives a precipitate, which occurs in yellow tables, melting at 82°.

#### HEMATOPORPHYRIN IN URINE.

Salkowski<sup>9</sup> describes three cases of women who passed this pigment in their urine. Six cases of this kind have been observed. In the present cases, Salkowski thinks that the presence of the pigment is to be attributed, in all probability, to the fact that the patients were taking sulphonal.

V. Harley and S. Torup<sup>10</sup> report two cases of women who suffered from severe nervous symptoms, ending in death. They were treated with sulphonal and chloral, and passed urine of a port wine color. The urine contained no albumen, sugar, bile, or blood. The pigment in these cases was, in all probability, hæmato-porphyrin.

#### EXCRETION OF BALSAMS IN THE URINE.

In a research carried out by R. Stockman<sup>11</sup> on human beings and rabbits with the four balsams of the British pharmacopœia (balsam of Peru, balsam of Tolu, prepared storax, and benzoin), it was found that balsam of Peru caused no disturbance of the kidneys, but the urine, if the dose given is large, gives a precipitate with nitric acid, as if albumen was present. The precipitate is, however, soluble in alcohol and in excess of acid. Prepared storax causes a similar condition. Treatment with benzoin gave no positive results, as, owing to the difficulty of dissolving it in suitable menstrua, it was impossible to give large doses. The same may be said for balsam of Tolu. In all cases the urine contained a large excess of hippuric acid. This research is of interest, as nephritis is said to have been set up in certain cases as a result of the use of these drugs.

## Reports of Societies.

### THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING, April 11, 1891.

DR. A. WORCESTER reported, by invitation.

#### A SECOND SERIES OF TWO HUNDRED CONSECUTIVE CASES OF MIDWIFERY.<sup>1</sup>

DR. SINCLAIR spoke of the value of the curette in cases where there were symptoms resulting from retained portions of the placenta or membranes. The first case in which he had used it was some six or eight years ago shortly after its use was recommended abroad, and before it had come into use for this purpose here in Boston. In this case he removed quite a large amount of debris whose decomposition was causing septicæmia, washed out the uterus with a corrosive sublimate solution and introduced iodoform with subsequent good results. Since then he has used

this treatment in a number of cases following abortion.

DR. GREEN was much interested in the carefully prepared report to which the Society had listened, and which suggested several topics for profitable discussion. His attention was attracted to the number of cases of post-partum hæmorrhage: it seemed to him that twenty-one cases of hæmorrhage out of a total of two hundred labors, that is to say one hæmorrhage in every ten cases, was a larger proportion than ought to occur, if the third stage of labor was properly conducted. He believed that the reader had reported the average length of the third stage in his two hundred cases to be about ten minutes, and herein he thought would be found the explanation of the frequent occurrence of post-partum hæmorrhage. There was a time, some ten years ago, when it was taught that the placenta should be expressed as soon as possible after the birth of the child; but he believed that a more rational understanding of the causes of post-partum bleeding had led the best teachers of the day to place no definite time limit within which the placenta should be removed, as this act should depend more on the condition of the uterus than on the lapse of so much time.

It is now well understood that post-partum hæmorrhage is most effectively prevented by securing the closure of the retro-placental uterine sinuses: while this closure may be, and sometimes is, accomplished by thrombosis, the more safe and physiological closure is secured by the retraction or rearrangement of the uterine muscular fibres, — a process which begins with the first contractions of the uterus and continues throughout the labor. We are truly told that hæmorrhage is likely to follow the rapid emptying of the parturient uterus, whether by nature or by art; and the reason why lies in the fact that in these rapid labors, there is not sufficient time for the normal retractive process to effectually take place. If, therefore, after the birth of the child, the placenta is hastily expressed, before a sufficient number of uterine contractions have brought about an effective muscular retraction, the sinuses will not be well closed and more or less hæmorrhage must necessarily take place. Much might be said in regard to the prophylaxis of post-partum bleeding; but he would restrict his remarks solely to the management of the third stage.

During the expulsion of the child the uterus should be supported and followed down by the nurse, and held or "cupped" by her while the medical attendant separates the funis and gives the necessary attention to the child. The physician should then take charge of the uterus, and by means of gentle massage re-awaken muscular activity. The uterine contractions may soon begin again; but if the labor has been long and tedious, there may be quite an interval of uterine inertia. During this period of uterine inactivity no effort should be made to remove the placenta, unless hæmorrhage should supervene, and this is not likely to occur if the placenta is undisturbed. Even after the uterus has resumed its functional activity, no immediate effort at expression of the placenta should be made, but the attendant should wait four or five contractions and give the uterus an opportunity to extrude the placenta *sua sponte*. If, after five or six good contractions, the placenta is still retained, it is then time to make use of Credé's method of expression, or, if this method fails, of manual extraction. When the

<sup>1</sup> See page 28 of the Journal.

<sup>9</sup> *Chemisches Centralblatt*, 1891, 1, p. 678. Abstract.

<sup>10</sup> *Journal of the Chemical Society*, London, May, 1891, p. 601, from *British Medical Journal*.

<sup>11</sup> *Journal of the Chemical Society*, London, May, 1891, p. 606, from *Laboratory Reports*, College of Physicians, Edinburgh, 3, 65-69.

third stage is conducted in this manner, the speaker believes that post-partum hæmorrhage is of rare occurrence.

DR. MINOT was surprised at the large number of cases of deformed pelvis. Among Americans he had found contracted pelves of very rare occurrence and also as far as his experience went this was the case among the Irish. He believed, however, that among the English and Continental nations deformed pelves were comparatively much less rare.

DR. WORCESTER replied that every one of the cases of deformed pelvis occurred among the foreigners who constitute in Waltham a large class among the operatives at the watch and cotton factories. They were Swiss, German and English, and in two cases Irish. He had never yet met with an American with contracted pelvis.

DR. J. STEDMAN agreed with Dr. Green that the too rapid completion of the third stage was a not infrequent cause for post-partum hæmorrhage, as he had found in cases where he had been called in by other physicians for this emergency. He himself always waited for nature, more particularly after etherization.

DR. SINCLAIR said that in the early days of his practice he had allowed plenty of time for the third stage. Later, however, he had adopted Credé's method of rapid delivery of the placenta, but did not doubt but that it was the cause of post-partum hæmorrhage in some cases. He had, therefore, within a few years returned to his earlier practice.

DR. TOWNSEND agreed with Dr. Green in the importance of not hurrying too much the third stage, although formerly when he had made a point of completing the third stage in five or ten minutes by Credé's method he had not been troubled by post-partum hæmorrhages. He was surprised at the large number of these cases reported by the reader. In the out-patient service of the Lying-in Hospital and Dispensary the externes, being often unable to perform the Credé expression properly, the third stage in many of the cases is practically left to nature. Out of the seven hundred or more cases delivered every year in this service very few cases of true post-partum hæmorrhage are met with.

DR. WORCESTER in closing, said: As regards the use of the curette after abortions it was often impossible to push the uterus down far enough to clean it out with the finger without the use of ether, whereas curetting is a very easy and painless process and withal an effectual one.

Of the two cases of septicæmia in his two hundred cases, the one fatal, the other not, he would say that in the former case the temperature remained normal till the fifth day, and he believed that septic infection did not occur during labor, but in the early days of the puerperium which was not under his control. The latter case occurred in a patient with miserable surroundings where he was obliged to work with every disadvantage. The septicæmia was slight and of short duration.

His list of lacerated perineæ was large owing to the fact that he included slight nicks in this class; and he had called any undue hæmorrhage a post-partum hæmorrhage, although he did not doubt but that many of these would not be so considered by other physicians.

In the absence of Dr. Strong a paper by him was read by the Secretary, entitled

# LAPAROTOMY, VERIFYING THE DIAGNOSIS OF PELVIC CELLULITIS.<sup>2</sup>

DR. SINCLAIR said that the name of Pelvic Cellulitis was given by Simpson. The criticism was easily made that it seemed impossible for the cellular tissue to swell to such a degree as to form such large masses, but the most severe blow to this explanation of the pathology was given by Bernutz and Goupil, who found that inflamed tubes and ovaries occurred in most of the cases.

That true cellulitis does occur in some cases is shown very beautifully by the case reported. Before the use of antiseptics cases used to occur during the puerperium. The number of cases of true pelvic cellulitis is, however, rare compared with the number of cases of pelvic peritonitis due to salpingitis.

## MASSACHUSETTS MEDICAL SOCIETY. THE ONE HUNDRED AND TENTH ANNUAL MEETING.

BOSTON, JUNE 9 AND 10, 1891.

(Continued from No. 1, page 16.)

### SECTION IN SURGERY.

THE Section met in Cotillon Hall, Dr. J. C. WARREN in the chair. The subject for consideration was

### THE DIAGNOSIS AND TREATMENT OF INFLAMMATIONS OF THE APPENDIX.

In opening the discussion, the Chairman said: When asked to preside over this Section it occurred to me that I could not select a better topic for discussion than the diagnosis of inflammation of the appendix. The subject has received an unusual amount of attention during the last few years, but has not as yet been discussed by this Society, and it seemed to me that its great importance, as a frequent and dangerous disease, made it desirable that the members of the Society should have an opportunity of coming to an understanding among themselves as to the proper mode of dealing with it. By way of introduction, I will cite two cases, which serve admirably well to show the difficulty of determining the moment when surgical interference should take place, and the treacherous nature of the disease.

I was called to the first case a few days ago. A boy ten years of age, had entered the hospital after an illness of about a week, characterized at the outset by a sudden attack of pain in the right iliac region, associated with nausea and vomiting, which had continued with more or less regularity until his entrance, at which time, there was some tympanites, "with tenderness everywhere, but most marked in the right iliac region, where there was an area of dulness, indefinite and small." (Record of Dr. W. L. Richardson.) Pain was constant, and he required morphia. At no time was there any great rise of temperature, and the boy's general condition seemed excellent after entrance. A great increase of pain, with rise of pulse and temperature, and a development of great abdominal distention occurred on the fourth day after entrance. On examining him I could find no dulness in the region of the appendix, or tumor in the rectum, which was well defined. An incision near the anterior superior spine

<sup>2</sup> See page 32 of the Journal.

of the ilium exposed the peritoneum, on opening which I found a large collection of foul pus, several ounces of which escaped. The pus cavity extended some distance between the coils of intestine; the appendix was found with its sloughing tip, and was excised. Dr. John Homans will tell you more about the subsequent history of the case. At last accounts the boy was doing well. This case illustrates one of the dangers of the disease, the supervention of a general peritonitis from breaking of the abscess into the peritoneal cavity.

The other case was reported by Dr. A. L. Mason, and illustrates the absence of severe constitutional disturbance, in a case that terminated fatally.

E. J. B., a printer, aged thirty-four, entered the City Hospital in the medical department, January 13, 1891. He said that he had had previous attacks of colic which were relieved by cathartics, and his trade led us to make a careful examination for lead which was negative in result. January 11th, he ate two cakes of Baker's chocolate, to which he attributed his present illness.

January 12th. Dull pain in left iliac fossa, and at night all over abdomen, with chills, nausea and vomiting.

January 13th. Entered the hospital, stating that he had taken an enema before admission, but had passed no wind for two days. The pain was dull over whole abdomen, which was moderately tense. No tumor. Urine high color, acid, 1027; large trace of albumen, excess of uric acid; much granular debris, and a few hyaline and granular casts.

January 14th. Three loose movements in the night. Pain was relieved by morphia. Much more comfortable. Abdomen still tense, but much less tenderness. Palpation negative. Rectal examination not painful, and no tumor could be felt. Occasional hiccough.

January 15th. Tenderness seemed to be more localized on the left, but no hardness could be felt, and nothing by the rectum to indicate abscess.

January 16th. Fifth day. Temperature became normal; pulse 88. He was able to assume any position in bed, and had slight general tenderness in lower abdomen, not localized. No induration was found. The bowels moved three times. No vomiting since entrance. Hiccough occurred at times. The same conditions continued until the sixth and seventh days, and on the eighth day two small loose evacuations were noted. Normal temperature and little pain. In the evening a sudden increase of pain occurred, with collapse, cold extremities and profuse sweating, panting for breath. The abdomen became distended. Perforation was inferred; and the patient died in four hours, from shock.

At the autopsy, forty-three hours after death, the appendix was found in the interior of the pelvis, on the right side, firmly adherent to the surrounding tissues and covered by coils of the intestine. It was gangrenous, and had several perforations. No foreign body was found. The surfaces of the intestine showed recent inflammation, and in places were adherent by a thin layer of fibrin. The peritoneal cavity contained some purulent material. The left kidney and ureter were absent. Right kidney enlarged; capsule not adherent; congested. Other organs normal.

In looking backward upon this case, the following questions suggest themselves:

(1) When the patient entered the hospital, was he suffering from the effects of perforation which tended

toward recovery, the fatal result being caused by the shock of a second perforation?

(2) Would examination under ether have cleared up the diagnosis?

(3) In the absence of many of the subjective symptoms, would most surgeons have deemed it advisable to operate?

(4) With a gangrenous appendix in his pelvis and old intestinal adhesions, would an operation have been successfully accomplished?

(5) How much significance should be attached to hiccough in abdominal cases?

(6) Do not cases of so-called ischio-rectal abscess result sometimes from appendicitis in the pelvis, and is not the usual course of such inflammations to find an outlet below?

Such an event is reported<sup>1</sup> by Dr. Vickery, in a somewhat similar case, but with more severe symptoms, in which an exploratory operation failed, and pus was evacuated two weeks later by rectum. In the same number of the JOURNAL an autopsy performed by Dr. John Homans, 2nd, discovered a condition much resembling that found in the case reported above, namely, "appendix sloughed and ruptured, fixed by old firm adhesions to the lateral wall of the pelvis, below the brim, and out of reach of any possible relief by operation, if such had been attempted."

Dr. D. W. CHEEVER said: It is a part of my early experience, that the frequency of appendicitis with subsequent fatal peritonitis, was first pointed out and insisted on, from twenty to thirty years ago, by the late Dr. J. B. S. Jackson. No operative interference was then thought of, and I can recall five cases, all fatal, from twenty-five to thirty years ago, whose symptoms of perforation and diffused peritonitis were plain and well-marked. Treatment then halted between first, leeching and mercury; second, opium.

Since operative measures were begun, I will recall, briefly, fourteen cases of my own:

(1) A boy of eighteen, in Hingham. Repeated attacks of inflammation in the right iliac region. No operation. Final recovery.

(2) A boy of nineteen, in the hospital. Repeated attacks. No operation. Slight tumor. Incomplete recovery.

(3) A woman of twenty-five, in the hospital. First attack. No marked tumor. No operation. Apparent recovery.

(4) A man of forty. Marked tumor in the right iliac region. No operation. Tumor shrinking, but traces remaining.

(5) A man of twenty-eight. Marked tumor. Symptoms of obstruction. No operation. Subsidence of tumor, and recovery under the use of calomel and salines.

(6) A boy of fifteen. Acute symptoms. No tumor. Tenderness in right iliac region. Operation. Pus evacuated. Improvement. Death from venous hemorrhage on the seventeenth day.

(7) A child of eight. Symptoms of over a week. Tumor in right iliac region. Operation. Encysted abscess. Recovery.

(8) A man of twenty-five. Acute symptoms. Operation, right iliac region, the fourth day. Pus. Adhesions. Protrusion of the large intestine in the wound. Recovery.

(9) Pain, tumor in left iliac region. Operation

<sup>1</sup> Boston Medical and Surgical Journal, January 12, 1888.

there. Abscess walled off. An orangewood toothpick found in the abscess. Recovery.

(10) Man of thirty-five. Symptoms left iliac region. Operation there. Localized abscess. Recovery.

(11) Prolonged symptoms of obstruction. Tumor in rectum. Tapped per rectum. No result. Finally abscess burst in rectum. Slow recovery.

(12) A woman of thirty. Acute general peritonitis. Operation. Death.

(13) A man of sixty. Latent symptoms of peritonitis. Old pericarditis. No tumor. No operation. Death. Slough of cæcum and general diffused peritonitis.

(14) A boy of twelve. General peritonitis, probably tubercular. Operation. Slow recovery.

Among six cases not operated upon there was one death; mortality, seventeen per cent. Of eight cases operated on, there were two deaths; mortality twenty-five per cent. Of acute diffused peritonitis, not operated upon and operated upon, all died; mortality one hundred per cent. The case of tubercular peritonitis operated on recovered.

Without relying much on this small number of cases, I venture to offer certain conclusions, I have arrived at, in my own mind, in a general review of my experience, which covers both the non-operative and the operative periods. The stages of the disease to be considered are: first, inflammation; second, perforation; third, walling in by lymph; or fourth, diffusion.

(1) The first twenty-four hours of medical treatment are those essential to preventing perforation, if inflammation has begun; or to promote the formation of adhesions, if perforation has taken place. This treatment is recumbency; strict diet; moist heat, incessantly applied; opium.

(2) If the vital resistance of the patient is good, we have prompt adhesions and a wall of lymph.

(3) If no encysting takes place promptly, we have a fatal diffusion.

(4) The presence of a recent tumor is a strong corroborative sign of appendicitis, but not a certain one. The absence of a tumor is an assurance of great danger, if the symptoms are acute.

(5) It is impossible to drain the peritoneal cavity.

Dr. R. H. Fitz: For practical purposes, the diagnosis of an appendicitis is based upon the recognition of the signs of a peritonitis, originating in the right iliac fossa. There may be other causes for such a circumscribed peritonitis, as intestinal obstruction from intussusception or strangulation. Again, the peritonitis may be of ovarian, tubal, uterine, vesical, even of rectal origin. The pain of an acute appendicitis may be suggested by a renal or biliary colic, while fecal impaction in the cæcum or a movable kidney may simulate the tumor. Despite these possibilities, an erroneous diagnosis is not often made.

During the past five years I have seen, chiefly in consultation, upwards of one hundred cases of appendicitis. It has been my usual experience to find the attending physician has made a correct diagnosis and has rightly appreciated the significance of the symptoms. At the same time, during this period I have made an erroneous diagnosis of appendicitis in three cases, and have failed to recognize it in a fourth case. As this experience has already been published, mere reference to it, at present is sufficient. Even in these cases the treatment was appropriate, although the immediate cause of the peritonitis symptoms was not cor-

rectly diagnosed. They are called to your attention, not because similar cases are likely to be encountered, but, because, in a considerable experience, such errors in diagnosis have been made.

What seems to me of even greater importance than accuracy of diagnosis, so easy in general, is the question when medical treatment shall cease and surgical treatment begin. Were perforation actually present, there would be no question in my mind; but I know of no diagnostic means by which one may absolutely determine at the outset, whether perforation is present or absent. In doubtful cases we should wait and treat the patient medically, until we get more direct indication for surgical treatment than may be present when he is first seen.

It is well to bear in mind that, of the cases just referred to, one-half received surgical treatment. Of the half which were treated medically, there was one-eighth which ought not to have been treated thus, since an abscess existed and was discharged, as a rule, into the intestine. But the abscess may discharge into the bladder, which is a very unfortunate complication. It seems to me that to permit the abscess to break into either of these cavities, if it can be avoided, is unwise.

But in most cases we must have more evidence to guide us in treatment than is to be had during the first twenty-four hours, or even later. We ought not to advise an operation at this time on the ground that a perforation may be present, since, in one-half the cases, at least, the patient may recover if no operation is performed. We ought to have this chance, and we should, therefore, wait until the development of the symptoms is such as to indicate that there is either a spreading peritonitis, or such a circumscribing of the peritonitis as to make it probable that the operation will be successful. In waiting for these symptoms, we are to watch the pulse, the temperature, the degree of pain and tenderness, their extension outwards from the region of the appendix, and the development of the tumor, which may take place in the pelvis, the region of the kidney, or the left side. If after three or four days the tumor has developed — and by this time it does develop, if it is to form — its recognition is easy. If there is then no tumor, the indications for operation offered by the constitutional disturbances are very direct.

In my opinion, then, it is desirable to wait for three or four days, at least, after the onset of the symptoms, in order to watch the progress of the case, for the purpose of deciding whether it will recover under medical treatment, or whether it will demand surgical treatment. This waiting is not only suggested by the experience in acute cases, but it is confirmed by those cases of chronic appendicitis in which the patient has localized disturbances for months and months. Every now and then there will be an acute exacerbation, often keeping him in bed for a few days. These, however, are the cases which, to my mind, are much better operated upon, if they are to be treated surgically, in the interval between the attacks, than at the onset of an acute attack.

(To be continued.)

PROFESSOR VIRCHOW. — A portrait medal of Rudolf Virchow is to be struck by Anton Scharff of Vienna, in honor of the great pathologist's seventieth birthday on October 13th next.

## MAINE MEDICAL ASSOCIATION.

THIRTY-NINTH annual meeting at Portland, June 9, 10, 11, 1891. The Association met in the Common Council Chamber, City Building, Tuesday, June 9th, and was called to order at 10.20 A. M., by the President, DR. SAMUEL B. HUNTER, of Machias.

The session was opened with prayer by Rev. Dwight M. Pratt of the Williston Church.

The morning hours were given up to the Treasurer's report, matters of routine business and a paper by DR. JAMES A. SPAULDING on

## EYE AND EAR OPERATIONS, AND CASES AT THE MAINE GENERAL HOSPITAL.

The question of "What cases demand immediate enucleation after injury?" claimed most attention in the paper and the following discussion.

The essayist illustrated the cases in which the eye may be allowed to remain, by a typical case, in which the injury, although extensive, was not in the ciliary region, was not deep enough to penetrate the vitreous and cause septic infection of the eye, no prolapse of iris or retinal detachment, so that there was a possibility of recovered sight and no probability of sympathetic inflammation. On the other hand, it was laid down as a rule without exception, that the eye of a child less than ten years of age, with a perforating injury of any sort, in any region of the eye, ought to be enucleated at once, by reason of the greater tendency of children to sympathetic ophthalmia.

Attention was called to the beneficial effect of resection of the optic nerve far back, in cases where enucleation of the injured eye has not prevented the transmission of the disease to the sound eye.

A number of cases of glaucoma were attributed to the thoughtless use of atropine in the inflammation of the eyes of elderly people.

## AFTERNOON SESSION.

The Address of the retiring President, DR. SAMUEL B. HUNTER, of Machias, dealt principally with the marked changes in medicine and medical teaching during the past decade, and deplored the lack of an efficient registration law for Maine. The idea was suggested, although admitted to be now impracticable, of a registration law which should be national in scope and administration.

DR. J. E. WALKER, of Thomaston, read a paper on

## PSEUDO-HYPERTROPHIC PARALYSIS.

DR. IRVING E. KIMBALL, of Portland, presented a paper on

## ADENOID VEGETATIONS OF THE NASO-PHARYNX.

The writer detailed the characteristic symptoms and physical signs of this affection in children, and exhibited photographs of illustrative cases, before and after operation.

## CATARACT, ITS TREATMENT, SURGICAL, HYGIENIC AND DIETETIC.

was the subject of a paper by DR. WILLIS B. MOUTON, of Portland.

Particular stress was laid upon the necessity of securing by hygienic and dietetic measures the best possible nutrition and nervous tone, not only to prepare for surgical treatment, but to secure the happiest results after its employment.

The conditions for perfect results in operation for cataract were outlined as: "Early operation," "modified linear section with iridectomy," "strict antisepsis," "limited confinement," "absolute non-interference with the eyes for four or five days unless demanded," "careful and restricted diet, mostly nitrogenous for two weeks before and after the operation."

In the discussion following, DR. JAMES A. SPAULDING called attention to the unpleasant results often accruing to patient and surgeon from removing early a commencing cataract when vision is fairly good, and substituting for it the disturbed vision consequent upon attempts to make the sound eye wear a glass to approach the new vision of the eye operated upon after it is fitted with a proper lens.

DR. J. J. COBB, of Milan, N. H., read a paper on

## INTESTINAL ANTISEPTIC MEDICATION.

A paper by DR. H. M. SAWTELLE, United States Marine-Hospital Service, on

## PROGRESSIVE MUSCULAR ATROPHY.

was illustrated by a patient exhibiting the characteristic appearance of this somewhat rare disease. The patient's hands had the peculiar clam-like appearance due to wasting of the extensors, and contraction of the flexor muscles. Face, hands and feet were of a purplish color, and the general hue of the skin all over the body was bronze; the skin was thickened and sensation almost everywhere blunted. This was particularly well shown over skin of back, buttocks and portions of thigh and legs. The muscles now involved in the atrophic process are those of the forearm, especially extensors of ulnar side, pectorals, deltoids, and trapezius, and those of neck, face and feet. The cause of the spinal degeneration in this case was regarded as specific.

## EVENING SESSION.

DR. ADDISON S. THAYER, City Physician of Portland, read a paper on

## GASTRO-INTESTINAL DISORDERS IN CHILDREN.

Milk sterilized by steam heat was urged as preferable to almost, if not all, other infant foods. Use of opiates, either by mouth or hypodermically, was deprecated; "the paralyzing of a bowel already feeble in its resistance against poisonous irritants seems justified neither by reason nor experience." Lavage of the large intestine by mild antiseptic douches was advocated, and met with cordial endorsement from members who were familiar with its use.

A paper by DR. M. C. GOODRICH, of Waterville, on

## CIRCUMSCRIBED OSTEO-MYELITIS INVOLVING LEFT KNEE-JOINT.

brought out the opinion of members as to the comparative merit of the various drugs used to resuscitate patients from surgical shock.

DR. A. P. DUDLEY, of New York, expressed preference for straphanthus hypodermically, over either whiskey or digitalis.

DR. L. W. PENDLETON, of Portland, believed no remedy to equal atropine in doses of one one-hundredth of a grain.

## SECOND DAY, JUNE 10TH.

By unanimous vote the Association adopted resolutions of congratulation to be presented to the New

Hampshire Medical Society at its approaching hundredth anniversary.

DR. W. E. ELWELL, assistant surgeon at the National Home, Togus, read a paper upon

#### HEART-STRAIN

based upon observations upon the veterans of the War of the Rebellion. It was stated that seventy per cent. of all admitted to these National and State homes had some abnormal and weakened condition of the heart. In a majority of cases the symptoms are only present at intervals or upon exertion, but in all cases so constantly manifest in their effects as to render its subjects incapable of labor, and predisposed to other diseases. This condition was attributed to over-mental and physical strain during service.

DR. I. T. DANA, of Portland, thought it would be difficult to show that a large proportion of these cases originated as a consequence of army service. He thought the same condition obtained in an equally large per cent. of cases in civil life after the changes of advancing years became manifest, and that over-stimulation and all unusual muscular or mental fatigue tended to exert an untoward influence upon the heart.

DR. E. M. FULLER, of Bath, said from his service as pension examiner, he believed malarial poison to have been more often the cause of this condition than excitement before or during battle.

DR. SARAH ELLEN PALMER, of Boston, read a paper descriptive of Apostoli's method of treating uterine and ovarian affections by the electric current.

DR. C. M. COBB, of Mechanic Falls, read a paper upon

#### HIP-JOINT DISEASE, A RESULT OF TRAUMATISM,

and exhibited a patient showing the favorable results of Gault's operation to relieve extreme abduction and flexion.

DR. GORDON, of Portland, favored Owen's plan of treatment by early aspiration of the affected joint.

The report of visitors to the Maine Insane Hospital by DR. A. J. FULLER, of Bath, elicited some criticism by members, of the action of the last legislature in refusing the appropriation for the new insane hospital at Bangor. The facts relative to this curious piece of legislation, after a lot had been purchased and plans drawn for the new buildings, seem to be that in the universal scramble for appropriations which characterized our last legislature, it was made to appear by those interested in certain schemes that this call for money was for the local interests of Bangor, and prejudices defeated a measure which the interest of humanity demanded, as every physician in this State can testify.

With a daily average at the Augusta Hospital of 612, and patients sleeping on the floors of the corridors in spite of the additional room gained by the new pavilions, the legislature has reason to feel far from proud of this performance.

#### ANNUAL ELECTION OF OFFICERS.

The list for 1891-92 is as follows: President, Dr. Edwin M. Fuller, Bath; First Vice-President, Dr. Bigelow T. Sanborn, Augusta; Second Vice-President, Dr. George A. Phillips, Ellsworth; Recording Secretary, Dr. Charles D. Smith, Portland; Corresponding Secretary, Dr. C. E. Williams, Auburn. Board of Censor: Dr. H. H. Smith, Machias; Dr. E. T.

Andrews, Gray; Dr. Charles Hutchinson, Portland; Dr. C. A. Peaslee, Wiscasset; Dr. C. D. Hill, Bethel. Committee on Publication: Dr. Charles D. Smith (*ex-officio*) Portland; Dr. F. H. Gerrish, Portland; Dr. A. K. P. Meserve, Portland; Dr. E. H. Hill, Lewiston; Dr. H. F. Twitchell, Freeport. Business Committee: Dr. F. E. Small, Portland; Dr. Wm. Lawrence Dana, Portland.

DR. S. C. GORDON read a report of

#### CASES OF ABDOMINAL SECTION DURING A THREE MONTHS' SERVICE AT THE MAINE GENERAL HOSPITAL.

These numbered fourteen in all, and there was but one death and that from cancer.

Among these of special interest was one in which over a foot of small intestine was removed with a tumor, the ends of the intestine closed by Lembert's suture, and anastomosis established by lapping the ends of the intestines together, making an opening about an inch from the ends and sewing together. The patient returned to her home well, having passed to recovery without accident, and is now pursuing her household duties.

Another patient was an infant of fourteen months, operated upon for relief of peritoneal effusion of tubercular origin. Patient was discharged recovered, but died in about two months from tuberculosis pulmonalis. Special stress was laid upon the treatment of peritonitis by salines instead of by opiates, regarding the disease as a condition to be treated independent of cause.

DR. G. A. COOMBS, of Brunswick, presented a paper on

#### DEPRESSED FRACTURES OF THE SKULL,

which urged immediate exploratory incision even if no cerebral symptoms presented.

DR. T. A. FOSTER, of Portland, presented the report of the necrologist. But three members have died during the year: Dr. O. E. Ross, of Rockport; Dr. N. R. Boutelle, of Waterville, and Professor Fordyce Barker, of New York.

DR. E. E. HOLT, of Portland, read a paper on

#### REMOVAL OF FOREIGN BODIES FROM THE VITREOUS.

The writer's opinion inclined to removal of such bodies by operation if the sight were destroyed even though they cannot be located or attracted by the magnet.

DR. F. H. GERRISH, of Portland, Chairman of the Committee on securing change in the Anatomical Law, reported the operation of the present law entirely satisfactory, and the risk of attempting to secure any change, too great to be invited.

#### EVENING SESSION.

This was devoted to the

#### ANNUAL ORATION

by DR. S. C. GORDON, of Portland.

Following the oration, a reception was given by the resident members, to the Association and visiting delegates and ladies.

#### THIRD DAY, JUNE 11TH.—MORNING SESSION.

The customary votes of thanks were passed and the session closed with the acceptance of the report of the Board of Censors and the adoption of its recommendations.

The appointments for the year are as follows: Orator, Dr. J. L. M. Willis, of Elliot. Delegates to American Medical Association, Dr. S. B. Hunter, Machias; Dr. B. F. Dunn, Portland. Neurologist, Dr. Alfred King, Portland.

The next meeting will be held as usual in Portland, but is changed to the second Wednesday in June instead of the second Tuesday, as heretofore.

The meeting was unusually large, and the papers of more than usual excellence. Delegates were present from the New York State Medical Society, from New Hampshire and Rhode Island.

## Recent Literature.

*Practical Electricity in Medicine and Surgery.* By G. A. LIEBIG, JR., PH.D., and GEORGE H. ROHÉ, M.D. 8vo, pp. viii, 383, with 253 illustrations. Philadelphia and London: F. A. Davis. 1890.

Our best treatises on electro-therapeutics have been written almost solely from the standpoint of the neurologist, and are now eight or ten years old. Since their publication, with the advance in the uses of electricity, the application of electricity to medicine and surgery has greatly increased. We need, therefore, a work which will deal with electricity from a much more general standpoint, and will guide us in the problems of electrolysis, electric lighting, electro-motors, and in all the various ways in which electricity is now brought into play. We hoped that the present work would satisfy this need. It should, as the present writers say, "be eminently practical, and should deal with such matters only as have a direct bearing upon the requirements of the practitioner. The book should be free from unnecessary technicalities, and only so much attention should be devoted to theory as is demanded in the explanation of such phenomena as are presented in the medical and surgical uses of electricity." In conclusion they say, "less attempt has been made to include everything written upon the subject than that nothing untrue should be contained within the covers of the book."

Unfortunately, the book comes very far short of answering these requirements. A hundred and forty pages are devoted to electro-physics. This is by no means a simple consideration. The writer begins by the statement that it is impossible to say what electricity is, which must be admitted, but if it be admitted that electricity, like heat or light, is a form of motion, and if the electricity derived from chemical action be first considered, the problems become simpler to those unskilled, as most physicians are, in the problems of physics. Instead of this the writer starts with the consideration of static electricity and lines of force, and the whole section is far from plain to any one unacquainted with physics. Its frequent formulae and its strictly technical considerations render it very difficult of comprehension to the ordinary physician, even though he know more of electricity than most physicians do. Although well equipped technically, and usually accurate in his statements, there is a striking want of harmony between this and the other sections of the book. In the description of the various cells no account is given of the Leclanché, which later on is spoken of as the best for a stationary battery. The

writer takes the only correct view of the question of the length of wire in a secondary coil, namely, that a longer wire interposes more resistance and diminishes the electro-motive force, yet later on statements are made, without correction, as to coils of long, thin wire giving the high tension current. Furthermore, many of the forms of apparatus, galvanometers, commutators, etc., described are suitable only for the physical laboratory, and not for the physician's use, while De Watteville's commutator for the combined currents receives no mention.

Technical and complicated as the first part of the work is, it is much better than the rest of it. This is largely a compilation, and much of it is of poor quality. The writer, for instance, claims that galvanism can directly influence the cord, and cites as a proof the benefit obtained by galvanism in tabes, whereas most neurologists doubt that benefit, and nothing indicates that galvanism produces any physiological effect upon the cord. Twenty-five pages are rather needlessly devoted to a verbal description of the motor points, which is far less clear than the diagrams. Some little attention is paid to the density of the current, but the accepted standard for the sizes of electrodes is not given, nor are Stintzing's tables of the different forms of the reactions of degeneration given. The chapter on special electro-therapeutics is confessedly a compilation, and the author does not even venture to act as a guide. Hence we find the methods suggested for the treatment of all manner of affections without regard to the suggester. Indeed the writer practically assents to the electrolytic treatment of urethral stricture, and seems willing to accept electricity as a panacea. As a minor suggestion we would urge the retention of the German notation in electro-physiology, as conducive to clearness and uniformity.

The book is a disappointment. It gives the impression of having been written in part by an electrician whose knowledge of the demands of medicine on electricity was slight and whose ideas as to the attainments of the physician and his ability to comprehend physics were greatly exaggerated, and in part by a man whose knowledge of electro-therapeutics was based, not on practical experience, but upon rather indiscriminate reading. It is not to be commended as a satisfactory guide to medical electricity.

*Plain Talks on Electricity and Batteries: with Therapeutic Index.* By HORATIO R. BIGELOW, M.D. 16mo; pp. viii, 85; 43 illustrations. Philadelphia: P. Blakiston, Son & Co. 1891.

This little work claims to be a "plain, practical presentation of a difficult subject." The opening chapter gives briefly a definition of the more familiar terms used in electricity; and then chapters are devoted to static electricity, galvanism and faradism. Some indications are given as to a choice of instruments, but these indications are incomplete. Nothing is said as to electro-physiology or electro-diagnosis. The therapeutic index is of some value, but it is incomplete and untrustworthy, and not a valuable guide for the inexperienced practitioner. The author's knowledge of the physics of electricity is not great, and he still clings to the idea that there is an actual difference in quality between the currents from the primary and secondary coils. The tyro in electro-therapeutics needs something more than this little volume, and the expert would find no use for it.

THE BOSTON

## Medical and Surgical Journal.

THURSDAY, JULY 9, 1891.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

## DIPHThERETIC PARALYSIS.

GUÉLER, in 1861, published an able memoir on diphtheritic paralysis, in which he endeavored to show that the paralysis which follows diphtheria has nothing specific about it, and that similar paralyzes may accompany all acute diseases. Diphtheritic paralysis, in his opinion, is the result of propagation of a pharyngeal, palatine, laryngeal, nasal inflammation to certain nerves — facial, palatine, trifacial, olfactory, auditory, vagus, branches of the sympathetic, etc. — or else it is simply the consequence of that asthenia which is consecutive to all grave maladies. It is hardly necessary to say that this view has long been abandoned.

By most authorities, it was regarded as the type of essential paralyzes (*sine materia*) till Charcot and Vulpian in 1862 discovered in a well-marked case (autopsy) the existence of neuritis of the palatine nerves, without any alteration of the nervous centres. This observation was subsequently confirmed by Lorain, Lionville and Lepine; and Sanné in his remarkable treatise based on these facts his theory of peripheral paralysis, or, as we should now call it, peripheral neuritis.

But Bahl, as far back as 1867, had found in a case of diphtheritic paralysis pronounced neuritis of the spinal nerve roots corresponding to the origin of the paralyzed nerves; there was extravasation of blood and thickening of the neurilemma. In 1875, Roger and Danaeschino in four autopsies noticed alterations similar to those which Bahl had described.<sup>1</sup> Similar observations were made by Dejerine in 1878. In 1876, Vulpian at the autopsies of three children who died of diphtheritic paralysis, noted "a modification of the nerve-cells of the anterior cornu of gray matter with rarefaction of the connective tissue of the external and posterior part of this cornu."

Three years later (1881) Landouzy as the result of his studies formulated for diphtheritic paralysis the following pathology: "In consequence of the diphtheritic toxæmia, the spinal cells suffer and undergo

alteration; they determine secondary degenerative lesions of the anterior roots, then of the nerves; but these lesions are superficial and susceptible of repair."

The most clear and satisfactory explanation of the paralyzes which follow diphtheria is that furnished by Roux and Yersin, whose researches go to show that the Klebs-Löffler bacillus is the cause of diphtheria, are now well-known. The paralysis is due, not to impregnation of the organism by the bacillus, but by the poison (tox-albumen) secreted by the bacillus. This has been proved by filtration of the soluble products of a diphtheritic culture, and the inoculation of animals with the filtrate which contains neither spores nor bacilli. Since the bacillus is not the direct agent of the toxæmia, but a product which it elaborates, we understand how the anatomical form of the pseudo-membranous affection has but a slight influence on the production of the paralysis, and how it is that the latter succeeds not only the grave and prolonged anginous attacks, but also the circumscribed and temporary localizations of the diphtheria. We also understand why the paralysis is not synchronous with the pseudo-membranous manifestations, but develops later when the microbes have disappeared, and after they have had time profoundly to alter the constitution of the blood.<sup>2</sup> In fact, before the paralytic accidents show themselves, there is a period of incubation of at least a fortnight, and sometimes longer.

Rendu, who has treated this subject at some length from the stand-point of latest researches, remarks that the old view which attributes the paralysis of the velum pendulum, pharynx, etc., to diffusion of an inflammation from the pseudo-membranous focus, is to be modified by the more correct doctrine that the poison is more likely to act first on the nerves nearest the point of inoculation, and in fact, it is often limited to these regions. But it is certain, on the other hand, that we have to do with something more than a mere local impregnation with the poison, as in the majority of cases we see the paralytic symptoms diffuse themselves progressively. It is equally certain that the diphtheritic poison acts exclusively on the nervous system by determining functional rather than destructive modifications.

## PETROLATUM.

At the time of the publication of the Pharmacopœia of 1880, different forms of ointment made from petroleum were in common use, largely under the names of vaseline and cosmoline. The official word, petrolatum, was introduced to describe certain of these products, the definition of the word in the Pharmacopœia being, "A semi-solid substance, consisting of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling of the lighter and more volatile portions from American petroleum, and purifying the residue. Melting point about 40° C. to 51° C."

Many similar products of petroleum now in common use do not come under this definition, and are commonly

<sup>1</sup> *Arch. de Gynecol.* Maladies des Enfants, t. III, p. 106.

<sup>2</sup> *Revue.* Leçons de Clinique Médicale, t. II, p. 335.

<sup>2</sup> Rendu: *Loc. cit.*

known by a variety of different names. At a recent meeting of the Philadelphia County Medical Society, Dr. John Aulde showed a number of specimens of these various products, and gave a description of their production and use.

During a visit to a large factory where these products are made from crude petroleum, Dr. Aulde was told by the workmen that when they have a bad cold they fill the nostrils with cosmoline and the trouble is quickly relieved.

These products are obtained by fractional distillation. The first twenty per cent. is called naphtha, and embraces several substances, such as rhigolene, benzine, naphthol, etc. The next fifty per cent. that passes over is composed of illuminating oil. This leaves about thirty per cent., fifteen of which is called neutral product, and fifteen per cent. called petrolatum stock. From this last cosmoline is manufactured. The neutral product is decolorized by filtration through bone black. It contains a certain proportion of paraffine wax. This neutral product corresponds closely to teraline, which has been extensively advertised as a remedy for consumption. The paraffine is removed by crystallization and freezing. Teraline may be of great benefit, because it contains this wax. There is also obtained a colorless product called glycoline, alboline, and by several similar names. This is an oil with the paraffine and coloring matter removed. It is made both as a liquid and as a semi-solid substance. The liquid paraffine of the German Pharmacopœia closely corresponds with this product. Preparations of petroleum stock may vary in color from white to dark yellow. It has been found that the colored petrolatum products produce discoloration of the skin. Cosmoline is perfectly innocuous, and may be taken into the system without harm.

In the discussion on this paper, Dr. S. Solis-Cohen said that crude petroleum is very valuable in the treatment of pulmonary complaints, especially of certain stages of phthisis. It is useful combined with iodoform. Two or three grains of iodoform may be combined with an equal quantity of crude petroleum, and administered in capsules. So-called alboline, or a modification of it called benzoinol, is useful as a vehicle for menthol and other agents to be applied to the respiratory mucous membrane.

Among other points brought out by the discussion, may be mentioned the fact that these products are the most valuable part of the petroleum distillation. The first seventy per cent. of the distillate is worth probably five cents a gallon, while the remaining thirty per cent. is worth from twelve to twenty-five cents a gallon. The quantity of these products manufactured has been steadily increasing.

A few years ago an effort was made in France to introduce petroleum products as vehicles for the hypodermic use of remedies. It was shown that the purified oils were innocuous, and it was shown that in this way twenty minims of purified creosote could be introduced at a single dose.

#### MEDICAL NOTES.

A JAPANESE PHARMACOPEIA will shortly be published. It is now under revision by the Central Sanitary Board of the Home Department.

ELECTROCUTION.—The second execution by electricity under the law of New York took place at Sing Sing on Tuesday. Four murderers were killed in succession. From the accounts of witnesses present it appears that in each case death was instantaneous and painless. The voltage was about 1,500 and the current continued for twenty seconds, and a little later repeated. The electrodes were placed upon the forehead and calves of the legs.

THE CENSORS OF THE COLLEGE OF PHYSICIANS, PHILADELPHIA.—The resignations of the Board of Censors of the College of Physicians have been placed in the hands of the Secretary. This action was taken because the college by a vote of forty-five to forty postponed consideration of the board's recommendation that a prominent member of the college, be censured for using slanderous language toward a member of the Fellows of the college. It is understood that the final retirement of the board will depend largely upon the action that may be taken by the college at its September meeting.

YELLOW FEVER IN GEORGIA.—It is reported that two cases of yellow fever have been discovered in Brunswick, Ga., one of the patients being a pilot who brought a foreign brig into port. Something like a panic has broken out, many families having left the place.

CHOLERA IN SPAIN.—The *Correio Medico*, of Lisbon, says that rumors of cholera are again beginning to be heard from Spain. Telegrams received in Lisbon from Valencia state that some "sufficiently marked" cases have occurred in that province, and the authorities at Madrid have taken steps to check the spread of the disease. As usual, the official press denies everything.

THE IMPORTATION OF DISEASE.—Surgeon-General Wyman, of the Marine-Hospital Service, has suggested, as a precaution against the importation of small-pox and other diseases by means of the baggage of immigrants, that the States for which the immigrants are destined, be furnished with a list of persons who come in vessels which have been or are infected or which come from ports at which contagious diseases prevail.

ABOLITION OF EFFEMINATE WORDS.—With the advent of women in positions formerly occupied only by men, the fair sex apparently consider it more manly to adopt masculine titles and masculine word-terminations. We have become quite accustomed to such words as chairman and doctor; but it seems as if they were carried too far, when we hear that Dr. Grace Danford, of Dallas, said, in an address to the Texas Medical Society, that she had had a predilection for the medical profession since her boyhood.

**HYPNOTISM IN FRANCE.**—The Society of Hypnotology will meet in Paris on July 20th, under the presidency of Dr. Dumontpallier. The business to be done will include the organization of a second international congress of hypnotism to be held in 1892. Among the subjects proposed for discussion are the following: "The Relations of Hysteria to Hypnotism"; "Criminal Suggestions and Penal Responsibility"; "The Reality of Maternal Impressions on the Fœtus."

**CIRCUMCISION IN EXCELSIS.**—A remarkable custom obtains in Turkey, says the *Medical Press*, which is carried out at the expense and under the direction of the Sultan. It appears that three of the Sultan's sons are "ripe for the operation of circumcision," whatever this may mean, and custom enjoins that all the other little Turks in the Empire who are of or about the same age as the young princes, shall submit to the same procedure at His Majesty's expense. In order to make due provision for this interesting event, a palace is fitted up for the occasion. The patients, who are said to number five thousand, are housed, clothed and fed for a week out of the Sultan's privy purse, and at the end of that time each receives a gift of money before being sent back to the bosom of his parents.

**THE ENGLISH CENSUS.**—The returns of the census for England and Wales have been so far made up as to show that there were on the day of enumeration about 29,000,000 inhabitants. The completed revised figures will not, it is said, materially change the total. This will make, in the last decade, an increase of about three million, or 11.64 per cent. This is the smallest recorded rate of gain since census-taking began in Great Britain. During the decade just closed there has been a decline of the marriage-rate. In 1881 it was 15.5 per thousand; in 1889, 14.7. In 1853 it was 17.9 per thousand. In the past fifteen years the birth-rate has fallen from 36.3 in 1876 to 29.7 in 1890. In 1890 the excess of births over deaths in England and Wales was but 308,267 against an average for the preceding five years of 366,013. The population is now three and a half times as large as it was in 1801.

**THE FOOD OF A STOWAWAY.**—The *Lancet* reports the autopsy on the body of an Arab stowaway, found dead on a vessel in London. Several patches of inflammation were found in the small intestine. In the cæcum were found twenty trousers buttons, three cog-wheels (apparently out of a watch, two of them one inch in diameter—these were double), one two-inch steel screw bent double and one one-inch screw, six pieces of a lock (the biggest piece was one and a half inches long and one-half inch broad), a circular piece of brass (one and three-quarter inches in diameter folded into four), several pieces of iron wire (four were one and a half inches in length), brass, and lead, and two key rattles on a ring, one inch in length. In the ascending colon, about five inches from the cæcum, were found a piece of steel wire one-eighth of an inch

in diameter, and three inches and half in length, bent double, and one small cog-wheel. The weight of these bodies together amounted almost exactly to half a pound. The body was much emaciated; no subcutaneous fat was present in chest or abdominal walls, or any fat round the kidneys. The deceased was quite unknown; no particulars could be discovered by the police employed to obtain evidence for the purpose of the inquest. There was no perforation of intestines, or any sign of disease in the colon.

**ETHER-DRINKING IN NORWAY.**—The *British Medical Journal* says that the theory has been more than once advanced that the origin of ether-drinking in Ireland can be traced to the success of Father Matthew's crusade against drunkenness in its ordinary forms. Alcoholic nature, driven out by his eloquence, returned in a new disguise, and the last state of the victims was as bad as the first. This theory has been called in question, but it receives accidental confirmation from what is at present happening in Norway. The sale of liquors is, in that country, encompassed about with more restrictions than that of the most deadly poison is with us; temperance, in fact, is the law of the land in Norway. But these people made sober by Act of Parliament, have now discovered how to get drunk without violating the law. Ether-drinking, according to a Norwegian contemporary, is becoming quite common in certain districts. The farmers buy it in considerable quantities, especially at Christmas time and on other festive occasions, and they treat each other and get drunk on ether, as they formerly did on potato or barley brandy. Ether is said to be drunk by young and old men and women, rich and poor. If this be true, it seems to point a moral which perhaps thoroughgoing temperance advocates have not taken sufficiently into account. Is there, after all, a grain of truth in Byron's thesis that "man being reasonable must get drunk," and can the moderate use of ordinary stimulants be suppressed only at the risk of the evil spirit, which has been cast out, coming back after the house has been swept and garnished, bringing with him seven devils worse than himself?

## Miscellany.

### AN UNRECORDED SYMPTOM OF PERTUSSIS.<sup>1</sup>

AMONGST the premonitory symptoms of whooping-cough authors mention conjunctivitis with excessive lacrymal secretion; but according to Dr. Huguin of Tourteron, to these ocular symptoms there should be added photophobia, with dilatation of the pupil, which he has observed pretty constantly in cases under his care, and that in the absence of all medicinal treatment, by belladonna or otherwise. His attention was first drawn to these hitherto unrecorded signs by the cases of two children, aged six and eight years respectively, in whom were present, in addition to the cough, not yet characteristic of the catarrhal period of the

<sup>1</sup> *Lancet*, June 13th.

disease, marked dilatation of the pupils, with photophobia. Some time afterwards, while still in professional attendance on the children, a servant girl aged eighteen, in the same household, in whom there was as yet no suspicion whatever of the ordinary symptoms of whooping-cough, was found to be affected with photophobia and dilatation of the pupils. Pertussis was, however, diagnosed, and this diagnosis was subsequently proved to be well founded by the supervention of the characteristic cough of a typical whooping-cough.

#### EXTERNAL MIGRATION OF THE OVUM.

VARICELA<sup>1</sup> concludes, from the results of ten experiments on female rabbits in which the ovary of one side and the tube of the other had been removed, that the external migration of the ovum, although rare, is incontestable. Only part of the ova are able to reach and enter the tube of the opposite side. Although it requires more time for the ovum to pass from the ovary to the tube opposite than to the tube of the corresponding side, still in doing so it retains its aptitude for fecundation. The external migration of ova experimentally produced was in no case the cause of extrauterine pregnancy. Granting the integrity of one ovary and of the opposite tube, not only fecundation, but also intrauterine pregnancy, are possible.

#### TACHYCARDIA.

FRAENTZEL<sup>2</sup> defines this disease as one without demonstrable organic heart lesion, in which repeated sudden attacks of rapid heart action occur and as suddenly disappear. The number of beats may reach one hundred and forty and over per minute. He considers most of the cases to be due to paralysis of the inhibitory fibres of the pneumogastries, and others to irritation of the accelerator fibres of the sympathetic. The former may sometimes be controlled by digitalis, or by pressure over either or both pneumogastries in the neck. The latter may frequently be controlled by a single dose of morphia. It is sometimes difficult, however, to determine to which of the two groups a case belongs. The author closes his article by quoting the following case: A man, aged thirty-five, complained for three months of sudden severe palpitation of the heart. The heart's dulness was increased; there were no murmurs. While in the wards, the patient had two attacks which responded to digitalis. A third attack occurred, with rapid dilatation of the heart, in which the patient died. The post-mortem showed dilatation of left ventricle and hypertrophy of right, much increase of fibrous tissue in both ventricles and fatty degeneration of the left.

#### CULTIVATION OF THE LEPROSY BACILLUS.

DR. BEAVEN RAKE and Dr. G. A. Buckmaster,<sup>3</sup> members of the Leprosy Commission, have during the last two months and a half been engaged in bacterio-

logical work at Almora Leper Asylum and in the new laboratory which has been built at Simla by the Government of India for the use of the Commission. They have now succeeded in cultivating the leprosy bacillus in serum from a blister. The first series of experiments, begun on March 31st, proved negative. On April 14th a blister was raised over a tubercle on the face of a leper at Almora, and another over normal skin on the back of the same patient. Specimens of the fluid from these blisters were taken in a sterilized capillary tube, and allowed to mix. Previous examination of blister fluid over a tubercle in this patient had shown leprosy bacilli. The capillary tube was kept at a constant temperature of 98° F., and was taken to Simla, where microscopic examination on May 2d showed some brightly stained leprosy bacilli and some turbidity of the liquid. On May 14th a tube of bouillon was inoculated from this tube of serum, and on May 26th there was an undoubted growth of leprosy bacilli on the surface of the bouillon. From this culture vigorous growths of leprosy bacilli were also obtained on gelatine and agar. Another capillary tube of serum prepared in the same way from another leper gave precisely similar results.

#### VOMITING OF PREGNANCY AND HYSTERIA.

KALTENBACH<sup>1</sup> holds that the clinical history and the "cures" of cases of uncontrollable vomiting of pregnancy indicate that the disease is essentially due to hysteria. Pregnancy involves physiological and psychological conditions favorable to the development of hysterical symptoms in a modified form. Hyperemesis is often cured by a process akin to suggestion, like ordinary hysteria. "Doing something," dilatation of the os, massage, etc., often succeeds if the practitioner gains the patient's confidence, and hosts of drugs have answered, apparently under the same conditions. On the other hand, all these vaunted medicines and operations have failed when employed by physicians who possibly did not possess as much tact as knowledge. Hyperemesis may suddenly cease if the patient be alarmed, as in a case of the author, where the patient was reduced to a skeleton; a day being fixed for the induction of labor, her friends frightened her by saying that she could not survive such an operation. The vomiting ceased. The same sudden arrest of hyperemesis was observed by Cazeaux in a young wife whose husband was seized with symptoms of strangulated hernia. In a third case, the vomiting ceased on the outbreak of an acute exanthematous fever. Kaltenbach describes a bad case where the patient, aged twenty-one, made an unhappy marriage, and was unkindly treated by her husband. Very severe vomiting set in during her first pregnancy, and she was sent into a hospital. It was suggested to her that she had lumps of unwholesome material in her stomach, and that their removal would cure her. Some milk was given to her, ceremoniously, and shortly after the stomach was washed out. Its contents bore no indications of either over-acidity or any abnormal ferment. The patient was then informed that all was right, and that the vomiting would not return. It ceased accordingly, and she was safely delivered at term. In short, Kaltenbach urges that hyperemesis gravidarum should

<sup>1</sup> Annali di Ostetricia e Ginecologia, October, 1890.

<sup>2</sup> University Medical Magazine, from Deutsche med. Woch., February 26.

<sup>3</sup> British Medical Journal, June 27th.

<sup>1</sup> Zeitschrift f. Geburtsh. u. Gynäk., vol. xxi., pt. 1.

be treated as a purely hysterical complaint. Prompt treatment is indeed necessary, for as in hysterical vomiting of non-pregnant women the patient may, if at first neglected, die of syncope or nervous exhaustion even when the vomiting has been stopped. But isolation from domestic cares and imprudent friends, with appropriate moral treatment, should be enforced before so extreme a step as artificial abortion is undertaken.

#### PARENCHYMATOUS ASPIRATION.

DR. ALBERT ABRAMS<sup>1</sup>, of San Francisco, describes, under the above title, a method of obtaining pathological products for diagnostic purposes. The method consists essentially of withdrawing by means of a hypodermic syringe, certain products from pathological formations in solid tissues, and the examination of these products by the microscope. The syringe used has a large barrel with a capacity of ten grammes, the object of the large barrel being to secure better suction. Products are removed by aspiration only, there is no harpoon action, and no destruction of tissue other than that produced by a needle.

After numerous experiments on animals, the author punctured the pathological lung more than fifty times for diagnostic, but mainly for experimental purposes, and the only ill effects observed were syncope in one case, hæmoptysis lasting a day in another case and circumscribed pains limited to the punctured points of short duration in two other cases. Parenchymatous aspiration was made with lungs the seat of tuberculosis, pneumonia and syphilis. In undoubted cases of tuberculosis of the lungs and bronchial lymphatic glands, the bacilli of tuberculosis could only be demonstrated in the aspirated products in about forty per cent. of the individuals punctured. Failure to demonstrate the bacilli in all cases was largely attributed to errors in technique, which were partially removed after further trials.

In some cases the syringe having been partially filled with an indifferent solution of salt this was injected into the punctured tissues, the needle remaining *in situ*; after waiting until the fluid had presumably taken up sufficient pathological products, it was then withdrawn. The number of bacilli found in the specimens examined was, as a rule, small, although in a few instances veritable colonies of the bacilli could be seen. Only two cases of croupous pneumonia were punctured, in both of which pneumococci were found. Tubercle bacilli were found in a case of cervical glands. By aspiration the bacillus lepræ was invariably found in leprous nodules, infiltrations and neighboring lymphatic glands.

The author concludes that parenchymatous aspiration is, when conducted with antiseptic precautions in all new formations not necessitating visceral puncture, a harmless procedure. In normal viscera, it is rarely attended with danger, owing to the elasticity of physiological tissues. Hæmorrhage may possibly follow aspiration in disease of the viscera, owing to diminished elasticity and pathological changes in the blood vessels, but the necessity for a correct diagnosis justifies in properly selected cases the slight risks attending parenchymatous aspiration. It is of value in the diagnosis of pulmonary tuberculosis with lung

consolidation, in which the sputa fail to reveal the presence of the bacillus tuberculosis, or when consolidation is present but no sputum, it may furnish the earliest evidence of the disease. In surgical tuberculosis of the lymph glands, bones, joints, skin, testicles and other structures, it is of undoubted importance, and it may be of value in the diagnosis of tumors, either superficial or deep seated. In amyloid degeneration of the viscera, it may furnish the only evidence of the affection. In malaria, typhoid fever and other infectious diseases, puncture of the spleen may prove of inestimable value in diagnosis. Leprous lesions of the external parts or viscera, may be correctly diagnosed by the aid of parenchymatous aspiration.

#### THE TREATMENT OF HÆMOPTYSIS.

In a paper published in the *Zeitschrift für Therapie* for April 1, 1891,<sup>2</sup> Professor Nothnagel calls attention to the fact that the most essential feature in the treatment of hæmorrhage from the lungs is that the patient should be kept absolutely quiet, should not be allowed to speak, the room should be kept at a moderate temperature, and he should eat nothing warm, and his food should be of the most readily digestible character, cold milk being preferable to anything else; and, in fact, he advises that for two days the diet shall be confined solely to cold milk. It used to be taught that coughing was of assistance in removing the blood from the bronchi, but this is now recognized as being an extremely hurtful teaching, and the first attention should be directed towards suppressing coughing, and for this purpose morphine is the chief remedy. When the hæmorrhage is only moderately severe, nothing further need be given to the patient than morphine; but when, as occurs in many cases, the hæmorrhage does not spontaneously cease, then other remedies have to be given.

The author at first calls attention to the remedies which ought not to be given, remedies which have been frequently recommended, and which yet may produce most disastrous effects. First of all in this connection is the sesquichloride of iron. When given internally, even if it is absorbed, which is extremely doubtful, it must form other combinations, and then will only produce the action of any other iron preparation which evidently would lead to an increase of the bleeding; and it is an old rule, but a good one, that individuals with a hæmorrhagic tendency must be very cautious in the use of iron preparations. The same remarks apply to tannic acid and alum. These remedies only serve to constrict the blood-vessels when applied in dilute solutions. So, also, inhalations of all kinds should be strictly prohibited on account of the more vigorous respiration which this mode of treatment entails, and the consequent danger of increasing the hæmorrhage instead of diminishing it. When, however, a violent hæmoptysis is to be treated, two substances are named, which may be of great service. The first of these is ergotin, which acts on the unstriated muscular fibre of the blood-vessels, and which may be given both internally and subcutaneously; the second remedy is the acetate of lead, which may be given in doses of from one-half to three-quarters of a grain. There is still another remedy which might be

<sup>1</sup>From a paper read before the Medical Society of the State of California, April 21, 1891.

<sup>2</sup>Therapeutische Gazette, June 15.

employed with some prospect of success, although Nothnagel states that he has as yet had no experience with it, and that is *hydrastis canadensis*. Atropine also, in subcutaneous injections of one sixty-fourth of a grain, has likewise been claimed to do good. As to the use of common salt, given in teaspoonful doses, it is not clear as to whether the arrest of hemorrhages, so frequently reported to follow its employment, are coincidences or consequences of the treatment. At any rate, it can do no harm, and may do good, when nothing else is obtainable. As regards the application of cold externally, he is very doubtful as to its value.

Finally, Nothnagel alludes to the heroic measure of bleeding from a vein to arrest hemorrhage from the lungs, a proposition based upon the observation that a violent hemorrhage in leading to syncope often causes the arrest of bleeding. Of course, such a procedure as bleeding for a hemorrhage from the lungs, can be dismissed without discussion.

### THERAPEUTIC NOTES.

#### TREATMENT OF GONORRHOEAL RHEUMATISM.—

In a discussion on this subject at a meeting of the Paris Société de Dermatologie et Syphiligraphie on May 14th, M. Jullien said that, having regard to the infectious origin of the disease, he had for the last five years systematically treated it with subcutaneous injections of bichloride of mercury with extremely satisfactory results. M. E. Besnier pointed out that joint inflammations of gonorrhoeal origin often spontaneously undergo rapid modifications, which made it very difficult to judge of the effect of particular remedies. In his experience local treatment was the most important therapeutic factor in such cases, and he placed most reliance on the method recommended by M. Lucas-Championnière, which consisted in touching the parts in a number of places with the point of the cautery, and then wrapping the joint in Vigo's mercurial plaster with cotton-wool dressing afterwards. M. du Castel said he had tried mercurial friction in one case without result, while in another case, in which, however, the inflammation was less severe, it had done a great deal of good.

**CARBOLATE OF CAMPHOR.**—This preparation is made<sup>1</sup> by adding one part, by weight, of carbolic acid to three parts of camphor, setting aside for twenty-four hours, and straining through gauze. It is a permanent liquid, with a specific gravity of 990. It is thoroughly antiseptic, and possesses unsurpassed germicidal powers. It may be locally applied to wounds, by means of cotton or gauze. When placed under the skin it produces anesthesia of the surrounding parts, which lasts for several hours. There is some soreness, but no abscess results. The slight smarting felt at first, shortly disappears. For hypodermic use, a little ether or pure alcohol should be added to the liquid. It combines readily with alcohol, ether, fixed and essential oils and petroleum derivatives, but *not* with aqueous solutions or glycerine. It readily dissolves menthol, cocaine, salicylic acid, chloral hydrate, iodoform and corrosive sublimate.

**ANTISEPTIC GAUZE.**—For plugging the uterus, Bar<sup>2</sup> has employed with advantage a gauze medicated

with retinol iodoform. It is used as follows: The gauze, after being boiled in strong carbolized water and well dried, is dipped in the following mixture,

R Retinol . . . . .	3 ii.
Wax . . . . .	3 iss.
Iodoform . . . . .	3 i. M.

Tampons made with gauze, prepared in this manner, are especially useful, inasmuch as they are apt to leave a good coating of iodoform upon the vaginal or cervical surface, and thus assure complete asepsis of the mucous membrane.

#### NEW PROCEDURE IN ABSCESS TREATMENT.—

The treatment of chronic or cold abscess by the method of aspiration and injection of antiseptic solutions, such as iodoform dissolved in ether, is a favorite plan of some French surgeons,<sup>3</sup> Dr. Picchaud of Bordeaux, has adapted the method with success to the treatment of acute inflammatory abscesses. Instead of a free incision of the most dependent part he aspirates the abscess, after which he injects a solution of 1 in 1000 of corrosive sublimate. For the past ten months he has invariably adopted this method with marked success. Even if the skin over the seat of the abscess be thinned and undermined, this is no bar to the procedure, for which he claims advantages that it is less painful, leads to more rapid healing, and leaves no traces of scar.

**BROMOFORM IN WHOOPING-COUGH.**—Nauwelaers<sup>4</sup> uses this drug in the following formula:

R Bromoform . . . . .	. gits. xx.
Alcohol . . . . .	. 5 iiss.
Sol. gum trag. }	
Syr. tolu. }	aa 3 ii. M.

Sig. One teaspoonful every hour.

The mixture should be well shaken before administration, and should be kept in a well-corked bottle. In adults, Nauwelaers gives the drug in capsules, each containing seven minims of bromoform. He gives the patient 14 capsules during two or three days. In children the dose should vary with the intensity of the attack and the strength of the child. At first 8-10 drops daily is usually a sufficient dose, but in a few days this may be increased to 20 drops, if found necessary.

<sup>3</sup> Lancet, April 18th.

Deaths reported 2,800; under five years of age 1,417; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoea, whooping-cough, erysipelas and fevers) 760, consumption 254, acute lung diseases 257, diarrhoeal diseases 508, diphtheria and croup 80, scarlet fever 38, typhoid fever 45, measles 33, whooping-cough 19, erysipelas 14, cerebro-spinal meningitis 14, malarial fever 10.

From typhoid fever Philadelphia 15, New York 7, Brooklyn 3, Boston, Baltimore, Cincinnati, Milwaukee, Washington, Nashville and Lawrence 1 each. From measles New York 20, Brooklyn 6, Boston, Milwaukee, Washington, Haverhill and Clinton 1 each. From whooping-cough Brooklyn 6, New York 5, Baltimore 3, Washington 2, Philadelphia, Boston and Nashville 1 each. From erysipelas New York 6, Philadelphia 3, Brooklyn 2, Boston, Cleveland and Chelsea 1 each. From cerebro-spinal meningitis Brooklyn 4, Washington, Worcester and Malden 2 each, Boston, Baltimore, Cleveland and Quincy 1 each. From malarial fever Brooklyn 5, Charleston 3, New York 2.

In the twenty-eight greater towns of England and Wales with an estimated population of 3,105,108, for the week ending June 14th, the death rate was 25.8. Deaths reported 1,235; acute diseases of the respiratory organs (London) 453, whooping-cough 118, measles 77, diarrhoea 135, diphtheria 34, fever 26, scarlet fever 22, small-pox (London) one.

The death-rates ranged from 14.0 in Brighton to 37.6 in Blackburn, Birmingham 29.9, Huddersfield 21.8, Hull 17.6, Leeds 19.1, Leicester 21.2, Liverpool 21.4, London 23.3, Manchester 20.1, Nottingham 27.0, Sheffield 22.9, Sunderland 22.6. In Edinburgh 21.9, Glasgow 25.1, Dublin 27.0.

In the twenty-eight greater towns of England and Wales with an estimated population of 3,105,108, for the week ending June 14th, the death rate was 25.1. Deaths reported 1,164; acute diseases of the respiratory organs (London) 434, whooping-cough 111, measles 79, diarrhoea 143, scarlet fever 38, fever 37, diphtheria 45, small-pox (London) one.

The death-rates ranged from 11.2 in Plymouth to 30.9 in New Brighton, Birmingham 26.9, Bradford 20.4, Hull 19.2, Leeds 19.1, Leicester 22.5, Liverpool 20.3, London 23.0, Manchester 20.0, Nottingham 20.0, Sheffield 21.3, Sunderland 17.9. In Edinburgh 26.7, Glasgow 25.1, Dublin 25.1.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 27, 1891, TO JULY 3, 1891.

Leave of absence for one month is granted Assistant Surgeon C. B. EWING, U. S. Army.

Upon the abandonment of Fort Davis, Tex., Assistant Surgeon J. O. SKINNER, U. S. Army, will proceed to Fort Clark, Tex., and there take station.

Assistant Surgeon EDWARD C. CARTER relieved from duty at Fort Walla Walla, Wash., and assigned to duty at Fort Canby, Wash.

## DEATHS.

ALFRED C. GARRATT, M.D., M.M.S.S., died in Boston, June 30th, aged seventy-eight. He graduated from the Berkshire Medical College, in 1814. He published a book on Medical Electricity, in 1830, and was the author of other works.

HENRY GAWEN SUTTON, M.B., F.R.C.P., Physician and Lecturer on Pathology at the London Hospital, died June 9th, aged fifty-five. He was one of the best known and popular teachers in London, and his work at the London Hospital, with which he had been connected since 1867, was of great scientific and practical value.

## Lecture.

NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

MR. PRESIDENT AND FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY:—The founder of the Shattuck Lectureship, whose memory is revered for his good works, and his loyalty to medicine and the welfare of this Commonwealth, has provided for special attention to the study of "diseases of its inhabitants," or "such other subjects" as this Society may select. Your Committee, in appointing me to the responsible duty of fulfilling its trust, has done me a great honor; I wish to express my high appreciation of it, and of the privilege of now addressing you. With the foregoing indications as to my subject I find that in New England there is probably no disease more prevalent than neurasthenia. It was the thesis of Beard, — to whom the world so largely owes the formulation of the accepted ideas of nervous exhaustion under the name given to it by him, — that it was mainly an "American disease." He believed that the chief and primary cause of its development and increase was "modern civilization," and that it had its "rise and growth" and highest expression, in the Northern and Eastern parts of our country. For the present occasion we may be permitted to accept these views so far as to find in them a reason for the fitness of this subject, as having a special local interest in this State of Massachusetts.

The subject of this lecture has been chosen with reference to its practical importance for the general physician, whose usefulness so largely and exceptionally lies in preventive medicine. My observations in the treatment of insanity have given me the conviction that in the commonly occurring and typical forms of mental disorder, which are of a functional and curable character, nervous exhaustion always plays an important part, both in the attending conditions and the causation. The treatment of these functional disorders, as far as the measures ordinarily regarded as therapeutic can go, is little else than the treatment of nervous exhaustion; this is the largest and most constant factor in producing the different groups of symptoms in disordered mental activity. Hence the practical usefulness of studying the varied manifestations of debility in nervous function, in its aspects prodromic to mental disturbance, both for the sake of cure of the existing disorder and for the prevention of the graver degree of exhaustion when insanity supervenes. Neurasthenia, according to Strümpell, is certainly one of the most frequent and important of nervous diseases.

*History.*—The subject to be discussed is neurasthenia with special reference to the significance of its early mental symptoms as affording important indications for diagnosis and preventive treatment. When Beard, in 1868, described under the term neurasthenia a wide range of symptoms of "nervousness," or conditions of nervous exhaustion, he used the term as designating "a chronic functional disease of the nervous system, the basis of which is impoverishment of nervous tissue in excess of repair." When, in 1880 and 1881, he published in his latest works an elaboration of his well-known views, there had been a very general acceptance of the principles they involved; and subsequently

many writers have classified neurasthenia as a neurosis, from its having no discoverable anatomical basis, and as signifying "nervous weakness." Beard's attempt to make of neurasthenia a distinct affection has, however, been much questioned. But by his originality and keenness of observation and analysis, he did his part in reducing a great array of data to definite principles, and initiating the wide application that is now being made of them. In respect to their extension and particularly their relation to insanity, a statement here of the position held by the earlier writers will give the key to the present understanding of the subject.

The "deficiency of mental control," "inability to concentrate the intellect on any task," the rapid fatigue from "the exercise of concentration," the "mental irritability" and "hopelessness" were recognized by Beard as notable symptoms. He also observed the fact that "neurasthenia may concentrate itself almost exclusively on the brain — cerebraesthesia — with the symptoms of morbid fears and impulses, depression, insomnia, fulness, headache, impairment of memory, decline in mental force and power of control." But while making many such precise specifications of most characteristic symptoms of melancholia in its milder manifestations he would only admit that neurasthenia sometimes leads to insanity; and that, while many cases of nervous exhaustion, with irritability, great depression, etc., tending downward to melancholia, come to the border line, they do not cross it as a rule, though they may do so in extreme cases. Some cases of melancholia in our asylums, he says, have been neurasthenics, and some are saved from becoming insane; but he claimed neurasthenia to be a "distinct disease," not "exhibiting the enormous defect that is seen in insanity."

The universally accepted principles of the "rest treatment" that have become so well understood since Weir Mitchell's first recommendation of them, in 1875, in a regular and systematic scheme of treatment, need no discussion here. All are familiar with the classical description<sup>2</sup> of his cases of nervous exhaustion and his specification of the essential elements of the treatment: — seclusion, certain forms of diet, rest in bed, massage and electricity. These measures have stood the satisfactory test of experience by their use in proper cases, in promoting "a liberal gain in fat and blood," of which "the gradual increase will be a visible result of the multitudinous changes in digestive, assimilative, and secretory power in which the whole economy inevitably shares." The great importance of the mental element in neurasthenia, and the widening application of the principles and plan of treatment in mental disorders are in fulfilment of Mitchell's own prophetic words that its sphere of usefulness was likely to extend beyond the limits originally set by him. The bodily conditions in insanity were not fully recognized as so largely those of nervous exhaustion as they really are; and Mitchell, Goodell, Playfair and others have held like views on this point. Mitchell wrote, "The true melancholias, which are not merely depression of spirits from loss of all hope of relief, are best left alone as far as this treatment is concerned. The nutritive failures which so often accompany them must be met by other means than rest, seclusion, etc.;" and this opinion was believed to be "sustained by some failures" on his part, and by the opinions of others.

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.<sup>2</sup> Fat and Blood, 1th Ed., 1885, pp. 38-43.

It is interesting to note, however, how largely the plan of treatment was addressed to the mental condition of the patients:—the manner in which their confidence and co-operation was gained, and particularly the seclusion, were for their mental effect. The need to “rest the organs of mind” was noted, and that “it is thought with the friction of worry which injures, and unless we can secure an absence of this it is vain to hope for help by the method” described. It was Playfair’s rule that the mode of treatment is “valueless without the cordial submissive assistance of the patient.” But we have now been taught by experience the efficacy of these measures even when enforced, in the nervous exhaustion of melancholia and mania. All writers have observed, as did Mitchell, that “many neurasthenic people suffer from any prolonged effort at attention,”—also the common loss of mental control. It is this characteristic lessening of the power of voluntary attention that becomes so significant in its diagnostic value, after we have observed its greater weakening in the graver exhaustion of melancholia. The common occurrence in the cases described of a brain hyperæsthesia as mental irritability, the depression of feeling, and despondency, are equally significant and characteristic of mental disorder from nervous weakness.

*Hereditary and Acquired Neurasthenia.*—The fact of hereditary predisposition was observed by all writers. Beard characterized it as a congenital weak resistance of the nervous system, entailing neurasthenia as a disease, or as constituting a nervous diathesis upon which the disease would be developed under deficient nutrition. But the idea of it as a clinical entity to be differentiated from other nervous and mental disorders has been broadened by some who regard neurasthenia as the primary condition of all nervous degeneracy,—not as itself a neurosis or a psychosis, but as the soil from which these may grow. There are two great groups of these affections, the hereditary and acquired. When inherited there may be organic modifications, permanent embryonic conditions, of the central nervous system as found in idiocy, etc., according to Arndt; or there may simply be a neuropathic predisposition with organic changes as yet undiscoverable,—a constitutional weakness and instability of the nervous system,—and this is hereditary neurasthenia. The form of acquired neurasthenia may occur in the constitutionally strong, and both forms may be due to any nutritional or toxic causes that can initiate a condition of weakness and irritability of the nervous tissue. Upon such a basis of organic and neurasthenic weakness, there may be engendered not only nervous disorders in general, but processes of degeneracy; and there may be like disorders and degeneracy in respect of those nervous functions which we call mental. All diseases being considered not as “entities,” but as morbid conditions and processes of which we observe the “symptoms,” we may regard neurasthenia as a disease either hereditary or acquired, and as manifested by many mental symptoms.

*General Relation to Insanity.*—The statement has already been made that in certain forms of insanity the bodily conditions are essentially those of nervous exhaustion. Of the great number of people, who are in neurasthenic conditions, it is true to say that only a certain proportion become insane. But conversely, the proposition may be equally true, that all people of previously sound health and constitutions, who become

insane with ordinary functional mental disorders, have their psychoses dependent upon neurasthenic conditions of the organism, whether the nervous power is annulled quickly by shock, or enfeebled more slowly by prolonged stress or other weakening influences. The fundamental condition here is acquired neurasthenia. When it is hereditary there is a plainer dependence thereon of mental symptoms that come more readily in such cases from stress, nutritive failure, etc. Insanity is always weakness from some cause or other, and the group of symptoms in any given case is a matter of the kind and degree of nervous exhaustion. We find the mental symptoms of neurasthenia in insanity, but being emphasized in unequal degrees in the latter condition, their import is more clearly revealed. Thus we may learn from the study of insanity how to understand and treat the lesser manifestations of nervous exhaustion in its earliest stages, as they are commonly seen by the general physician. In the study of the mental conditions having a common etiology, it will be of advantage if in either case the source and genesis of the symptoms can be made clearer. The present endeavor is to make such a contribution to the subject from observations of mental disorders dependent upon neurasthenia. It will first be necessary to consider some of the fundamental principles that must be regarded in the analysis and interpretation of the data of clinical observations.

*The Animal Organism a Mechanism.*—The animal organism is regarded biologically as a mechanism which is stimulated to action by its environment, and in turn, acts upon it. Underlying all these phenomena is reflex action of the nervous system, and physiologists generally agree to consider every action as aroused by some definite cause or stimulus.<sup>3</sup> The mechanism, as a whole, is regarded as made up of minor mechanisms, when studied by the physiological method which reasons from structure to functional activity, and from activity back to structure. But the physiologist must observe many “activities” for which he can, as yet, only infer corresponding elementary parts in the organism, the relations of which he can only study as they are represented by their activities. This is peculiarly true of the mental mechanism and its activities, such as attention and memory. We have to assume that every manifestation of mind is correlated to a definite mode and sphere of brain activity; and we can conceive it as constituting a mental mechanism. We can conceive also all the systems and organs of the body as so many co-ordinated mechanisms,—as the muscular, circulatory, and digestive mechanism, etc. The nervous system as a mechanism, made up of many local adaptations to structure and function, presents a like variety of minor mechanisms, with peripheral and central elements of co-ordinated ganglia, nerve-fibres, and nerve-endings. Any one of these minor nervous mechanisms may become neurasthenic from excessive or irregular exercise of its functional activity; the end-organs of the special senses, and any part of the peripheral or central sensory apparatus may become separately fatigued,—allowance being made for the resistance to fatigue of conducting nerve-fibres.<sup>4</sup> The same is true of the nervous elements of the motor mechanisms. All the inhibitory mechanisms, and particularly, in the sympathetic system, neurasthenic conditions of the inhibitory vaso-motor

<sup>3</sup> Sedgwick: *Art. Reflex Actions*, *Ref. Hand Book of Med. Sciences*.

<sup>4</sup> Bowditch: *Jour. of Physiol.*, vol. vi, p. 123.

centres are especially important in the causation of both local and general disorders. The metabolic processes in general may suffer from central weakness of innervation and control; and there may be neurasthenia of such special organs as the heart, stomach, and liver. Thus there are many forms and degrees of the phenomena of nervous exhaustion classified under the divisions of cerebral, spinal, or general neurasthenia; and hence neurasthenia has been defined by Ziemssen<sup>6</sup> as "a functional weakness of the nervous system, varying from the slightest degree in single localities to entire loss of strength in the whole nervous system." But though the symptoms vary greatly according to the functions of the part affected, we are always led back to one principle:—the weakness of the nervous system from some cause, whatever it may be.

The physiological basis of these phenomena is the principle of the storage and discharge of energy of muscle and nerve. This accords with the biological theory that all function is due to chemical changes taking place within the organism, and that the functional activity of a specialized tissue depends primarily upon these changes in the individual cells. The fundamental idea is, that in the resting state the cell elaborates highly complex compounds, and that these break down to yield the energy by which the cell does its work.

*Importance of Physiology and Chemistry.*—Such being the character of the organic mechanism the difficulties have been very great in gaining an understanding of these affections. Writers have dwelt chiefly upon the facts, clinically observed, of the expenditure of nerve-force and "the waste of nerve-tissue in excess of repair"; and emphasis has been laid mainly upon the nutritional elements of the problem. But while they have recognized the necessity of treating the mental conditions upon which they made clinical observations, the larger import of these mental symptoms has escaped full appreciation. Moreover, in the search for lesions explanatory of the most marked disturbances of function, anatomy and pathology are as yet disappointing. Physiology offers greater aid, and by the new laboratory methods not only bodily but mental activities may be studied, in advance of our knowledge of the structural mechanisms upon which they depend. Now, newest of all, comes the science of bacteriology with its wonderful revelations, and the new discoveries in organic and physiological chemistry; they promise to throw great light upon these mysteries of our problem.

*Two Essential Considerations.*—The present status of this problem gives us two important indications:—first, we cannot correctly conceive the existence of a condition that may be called "pure neurasthenia" as a matter of simple weakness from over-use, and inadequate rest and nutrition, but we must make large account of the presence of toxic materials in the tissues as the immediate products of this normal exercise;—and second, we must take into account also the nature and manner of production of the mental symptoms common to neurasthenia and insanity, and their significance and value must be better understood and appreciated. There is time here for only the briefest mention of some of the conclusions reached by the newer investigations in the different branches of this complicated problem; these may serve to indicate the grounds of the arguments in support of the two foregoing propositions.

<sup>6</sup> Neurasthenia. Wood's Monographs, vol. 1, 1889, p. 534.

1. *Toxic Elements in Normal and Pathological Fatigue.*—The normal organic mechanism, represented by a healthy adult, may be taken as a standard for observation. When it is stimulated to activity there may be observed the phenomena of use, and of stress from over-exercise. Beginning with the peripheral muscular mechanism, physiology teaches us that fatigue is not the only result of muscular contraction. Noxious products are always yielded as the results of the attendant chemical change in the muscle substance, by the decomposition of certain parts of which, the latent energy is set free and expended in mechanical work. The restoration to the normal state is not alone through rest, and processes of repair by nutrition and the rebuilding of the complex molecular substances of the muscular tissue, but the blood current carries off the immediate waste products, obstructive to function, while it brings new raw material.<sup>6</sup>

*Normal Fatigue.*—A muscle made to contract repeatedly, whether by electrical stimulation or voluntary effort, will yield regularly lessening contractions until it ceases to respond and is said to be "exhausted." In the case of voluntary contractions there is central fatigue also from the expenditure of energy in mental effort. The difficulty has been to distinguish between the central nervous fatigue, and the peripheral fatigue of muscles; but Mosso,<sup>7</sup> Maggiora,<sup>8</sup> Lombard,<sup>9</sup> and others have shown that the "curve of fatigue" is alike in each case. They have demonstrated experimentally in man, that there is an intimate connection between the fatigue of the central nervous system and that of the muscles,—that there is loss of power by exercise in both peripheral and central mechanisms,—and that the effects in each may be studied separately. When certain muscles were experimentally fatigued by long-continued work under both electrical and voluntary stimuli, it was found that other muscles not exercised were also affected and their power lessened, as by a transmitted toxic influence. It was found also that human muscles have an excitability and energy peculiar to themselves, and that they weary independently of the excitability and energy of the nerve-centres. This shows that the muscles are the seat of certain phenomena of fatigue which, thus far, have been thought to arise in the central nervous system and to belong essentially to it. Under prolonged exercise there is lessened sensitiveness as well as diminished power.

In a man subjected to severe mental work, it was found that the muscles, which had been inactive, were weakened by it. The result of such experiments is regarded as going to show that a poisonous material, produced by chemical changes in the brain, enters the circulation, and, acting upon the muscles, weakens them. These demonstrations are also in accordance with the generally accepted physiological principle that the central nervous mechanisms, as do the muscular, undergo a regressive metabolism of tissue upon exercise, and that this is also of an oxidative character with toxic waste products.<sup>10</sup> There is also in nervous centres a like loss of normal excitability with fatigue and exhaustion.

*Physiological Shrinkage and Recovery of Cell-con-*

tents. — A further demonstration of the physiological changes in nerve-cells is being made by Hodge,<sup>11</sup> in his experiments begun in 1887, which are of the most significant interest. The electrical stimulation, in frogs and cats, of a nerve going to a spinal ganglion caused, after a number of hours, a marked shrinkage of the nerve-cells, particularly of the nuclei, which lost forty per cent. of their bulk; the cells themselves, though decreased but little in size, showed extreme vacuolation in the cell protoplasm; and the nuclei of the cell capsule shrank to a noticeable degree. The change in the cells was found to be generally in proportion to the severity and duration of their stimulation. It was shown that in a subsequent resting state the cells recover their normal appearance, but by a slow process. After five hours of severe work and a shrinkage of 48.8 per cent. in the nucleus, recovery required twenty-four hours. In the cells of a worked ganglion there are different degrees of shrinkage of the nuclei, — from five to eighty per cent. of original volume; in the latter the protoplasm was riddled with vacuoles and the nucleus shrunken to a densely staining speck. The spinal ganglia of pigeons and English sparrows, after normal exercise, showed exactly similar changes; — the difference between the condition of the sparrows' cells, when rested in the morning, and fatigued at night, being much more marked, on some occasions, than could be obtained by the most severe electrical stimulation. Sadowski has obtained the organic changes, of neurotic coagulation and vacuoles in central cells, from peripheral stimulation, mechanical and electrical. There can be no doubt that such visible changes are accompanied by chemical reactions also; the worked cells took the staining differently, and it is probable that new granules were formed taking a darker staining. The evidence is important, that all these changes are normal, and correspond with the daily rhythm of rest and activity, — sleep and waking.

These physiological and chemical explanations of the conditions following exercise, are supported by an evident diminution and removal of the substance of the nerve-cells as a normal process. It is shown that the actual expenditure of energy, muscular or nervous, is a factor which has always joined to it a toxic element in the products of the changes normally caused in the tissues by functional activity. There may be local areas of toxic influences hindering or inhibiting the functions of distinct peripheral or central mechanisms; and the blood becoming charged with them more general effects may be produced.

These are the common phenomena of a normal active life, in the daily round, from morning rest, vigor and alertness, to evening fatigue, weakness and heaviness, — both in mind and body. The restoration of normal conditions, with the re-storage of energy, comes through nutrition, furnishing new raw material, — rest, to stop the expenditure of energy and give time for the chemical building up of cell-contents, as well as for the removal of accumulated waste products, — and sleep, to hold in abeyance the general normal irritability, and afford effective repose to all tissues whose activities can be spared from the vegetative life. Unused muscle wastes; when used it grows. The nutrition of a muscle is favorably affected by its functional activity.<sup>12</sup> A wholesome degree of fatigue is normally attendant

upon physiological use, through increased blood-supply and reactions promotive of nutrition; this may be characterized as normal fatigue in contradistinction to the more pronounced effects which constitute exhaustion.

(To be continued.)

### METATARSAL NEURALGIA, OR "MORTON'S AFFECTION OF THE FOOT."<sup>1</sup>

BY E. H. BRADFORD, M.D.

THE title "Morton's Affection" could properly be used, as the affection was first thoroughly described by Dr. Thomas G. Morton, of Philadelphia; but a personal name is, as a rule, to be avoided, if possible, in defining a disease, and it is for this reason that the term "metatarsal neuralgia," has been preferred. The disease consists of a form of neuralgia of the foot, quite clearly marked in its symptoms and often exceedingly distressing. The affection is not an uncommon one, but has hitherto attracted but little attention.

It is somewhat singular that an affection which is not infrequent, in these days of thorough investigation of all ailments, should have attracted but little attention either in the researches of surgeons or of neurologists. The cases are usually classed among the ill-defined hysterical or nervous affections, and not thoroughly investigated; or they are deemed to be gouty, as in the minds of many practitioners are frequently all painful affections of the toes.

The pain is situated at the base of the fourth toe, and often, in severe cases, radiates up the leg. It may be of a dull character, or it may be throbbing and extremely severe. Ordinarily the pain is spasmodic, or is worse at intervals. At times, in some instances, it is so severe as to entirely prevent walking, and the patient has to sit down and rest for a few moments. The pain is usually not severe at night. It is aggravated usually by local pressure over the head of the metatarsal foot, or by squeezing the foot. On inspection of the foot nothing can be observed.

Dr. Thomas B. Morton, in the *American Journal of Medical Sciences*, January, 1876, reported a number of cases, which he classified as a peculiar and painful affection of the fourth metatarso-phalangeal articulation. His attention was first directed to this affection in 1870. Cases of the mild form were reported by him to be bearable; they may, however, develop into the severe form. Attacks of pain, in the mild cases, are followed by periods of complete immunity, but neuralgia reappears again at intervals. In the severe form, cases are so from the commencement, frequently following a sprain or a twist to the anterior portion of the foot. In certain cases the affection appears to be dependent in part on ill-fitting shoes.

Dr. Morton has given an anatomical explanation of the symptoms, which are manifestly due to a neuritis caused by the pinching or bruising of a nerve by the head of the fifth bone. The occurrence is due to the fact that the metatarso-phalangeal joints of the first, second and third toes are found on almost a direct line with each other, while the head of the fourth metatarsal is from one-eighth to one-fourth of an inch behind the

<sup>11</sup> *Ann. J. of Psychol.*, May, 1888; May, 1889, and Feb., 1891.

<sup>12</sup> *Footst.*, Op. cit., p. 116.

<sup>1</sup> Read at the Meeting of the Surgical Section of the Suffolk District Medical Society, April 1, 1891.

head of the third, and the head of the fifth is from three-eighths to half an inch from the head of the fourth. The joint of the third, therefore, is slightly in advance of the joint of the fourth, and the joint of the fifth is considerably behind the joint of the fourth. The fifth metatarsal joint is so much posterior to the fourth that the base of the first phalanx of the little toe is brought on a line with the head and neck of the fourth metatarsal, the head of the fifth metatarsal being opposed to the neck of the fourth. There is very slight lateral motion to the first three metatarsal bones. The fourth has greater mobility, the fifth still more than the fourth, and in this respect it resembles the fifth metacarpal. Lateral pressure brings the head of the fifth metatarsal and the little toe into direct contact with the base of the first phalanx and the head and neck of the fourth; to some extent the extremity of the fifth metatarsal rolls above and under this bone. The branches of the external phalangeal nerve are fully distributed to the little toe and the outside of the fourth. There are numerous branches of this nerve equally lodged in between these toes, and they are liable not only to be unduly compressed, but pinched by a sudden twist of the anterior part of the foot. Any foot movement which suddenly may displace the toes when confined in the shoe may induce an attack of this neuralgia. In some cases no abnormality or other specific cause for the disease has been detected.

The most clear description of the symptoms of the affection is one furnished to Dr. Morton by a physician who had suffered from this affection for some time. The gentleman's first attack occurred during his boyhood, and was produced by the tight lacing of skate straps. On unbuckling the straps the cramp was at first soon relieved, and it was thought nothing of. But on a continuation of this system of squeezing by tight straps and tight boots, and riding for hours on horseback with the flexors of the leg and foot in violent action, and the toes turned in, the attacks became more frequent, more painful, and the abnormal condition of the parts more chronic. The causes determining the accession of the paroxysm were the wearing of a badly-fitting boot, especially if the sole was narrow; a long and fatiguing walk, particularly on a hot day over a hot pavement; a long ride on horseback; a wet boot sticking to the sock; a wet sock sticking to the toes; long continued flexion of the knee-joint, as in a railroad car, carriage or lecture-room; treading on an uneven surface, as a cobble pavement; and if the nervous system be depressed from any cause, these exciting causes would act more powerfully. Symptoms of an attack were most intense pain, with increase of torture on the use of the boot-jack; and with all this no redness, no swelling, no abrasion of the skin, no callosity, no visible displacement of the bone, at least after removal of the boot. The suddenness of the attack was noteworthy. The patient was often obliged to remove his boot, sometimes in company, sometimes in his carriage; he has been obliged to sit down on a curbstone and remove the boot; he has dismounted from his horse and sent home for slippers; he has tied his horse to a tree and lain on the ground, unable to ride farther. All tight boots did not cause an attack, and some tight boots were favorites, because they would not let "the toe out of joint." The remedies which gave relief were the removal of the boot, the manipulating of the toes, straightening them out. When inconvenient to take off the boot, he found

that grasping the foot tightly round the metatarsal region would answer, and sometimes a circlet of india-rubber band, binding the foot round the instep. Putting on a dry boot and dry stocking was of great benefit, and the boot should be well sprinkled with powdered soapstone before putting it on. Frequently an attack has been relieved completely without other means than rest and a cup of strong tea.<sup>2</sup>

Symptoms vary to an extent but the above description will serve as a type for a number of cases.

The frequency of the affection in women rather than men was observed by Dr. Morton, and attributed, not only to the greater delicacy and pliability of the foot as compared with that of men, but also in a measure to the custom of wearing tight shoes. Of 15 cases, 13 were in women and two were in males. All of the patients were those who were accustomed to the luxuries of life.

Dr. Erskine Mason, of New York, reported a case of metatarsal neuralgia of the joint to the second toe, and Dr. Morton has seen a few cases in the joint of the third toe. Dr. Morton found, on inquiry among shoe dealers, that the peculiar condition has not infrequently been seen by them; but singularly it is not a case of disability among soldiers, on the authority of Dr. Billings.

Somewhat similar symptoms are described by Dr. Auguste Pollosson, of Lyons, though hitherto unrecognized as belonging to a distinct affection, he believes, anterior metatarsalgia, as he terms it, has a very real existence, being capable of putting a patient who has the misfortune to be its subject to a good deal of serious distress and inconvenience. He describes an instance in which a medical man, twenty-nine years of age, has suffered from this affection for some years. It gives no trouble when the foot is at rest and without a shoe, but it is usually brought on by wearing boots and by walking a good deal. It is much more likely to occur when going down than when going up hill. The pain comes on suddenly, a feeling of something having given way in the foot accompanying the onset, together with a kind of grating sensation. After this the patient walks lame, for all pressure of the anterior part of the sole of the foot on the ground is very painful. If walking is persisted in, the pain increases, until in a few minutes it attains its maximum, rendering all further attempts at locomotion absolutely impossible. The symptoms can be removed by taking off the boot and squeezing the forepart of the foot, especially if the heads of the middle metatarsals are at the same time pressed upwards by the finger. When this is done a kind of grating is again felt, together with a sharp twinge of pain, but almost immediately afterward the pain entirely ceases. The cause of the affection is evidently a certain laxity of the transverse metatarsal ligament, which permits a partial infraction of the arch formed by the heads of the five metatarsals, one of the middle ones, probably the third, becoming dislocated downwards and compressing the nerves running along each side of it against the heads of the neighboring bones. Dr. Pollosson mentions a somewhat analogous case, where a young growing girl suffered from a hammer toe from a similar laxity of the metatarsal ligaments.<sup>3</sup>

<sup>2</sup> In addition to this clear statement of the affection by Dr. Morton, see the *American Journal of Medical Sciences*, 1876; the "Surgical Record of the Pennsylvania Hospital," 1880, p. 169; and the *Philadelphia Medical Times*, October 2, 1886.

<sup>3</sup> *London Lancet*, March 2, 1887, p. 436.

Dr. Pollosson reported some relief from the use of a soft pad worn in the sole of the boot.<sup>4</sup>

A few English writers, commenting on the paper of Dr. Pollosson, have reported experience similar to his, and seem to regard the affection as due to the sinking of the plantar arch.

The affection may be similar simply in the symptoms of neuralgic pain, but different as to causation; or "anterior metatarsalgia" may be another name of the affection first described by Dr. Morton, the difference between the two writers as to the pathology being one due to the difficulty of obtaining anatomical proof in the cases afflicted.

As but little has been written on the subject, evidence confirmatory of Dr. Morton's observation will be of use; and for this purpose the following cases are reported by the writer.

The symptoms presented exactly correspond to those mentioned in Dr. Morton's cases, except that in those that have come under the writer's observation, the symptoms were not the result of an accident or the twisting of the foot, but were of the idiopathic and chronic type.

Of the 16 cases, 13 were in women; four were nurses; one a female book-keeper, obliged to stand all day. One of the men was large and of heavy build. The patients were all persons enjoying health; in none was there any evidence of gout or rheumatism.

In the cases which have come under my observation the results of treatment, as well as the symptoms and localization of the severest point of pain, would appear to confirm the view of Dr. Morton, to the effect that the symptoms are due to a pinching of the metatarsal nerve rather than to a "flattening of the tarsal arch." The pain was essentially neuralgic in character, and in all cases relieved if the boot was removed, although the patient stood upon the floor on the bare foot, and without support to the tarsal arch. In none of the cases was there flat-foot present.

CASE I. Miss F., accountant, age twenty-eight. Is obliged to stand all day. Person of excellent health, but for several years has suffered acutely from pain in her right foot, radiating from the base of the fourth toe. This is at times intolerable, so that she is obliged to remove her shoe, and when new shoes are worn the pain becomes intense. Some shoes she becomes accustomed to, and others it is impossible for her to use. Her shoes are made with great care, but she has a certain amount of pain at all times, at some times such an amount of neuralgia as to make her willing to submit to any operation for relief. Is unable to tell what shoes may help her, and new shoes are always uncomfortable; some old shoes she can wear for a while. She has at times been obliged to sit down in the street and rest for a short time until the attack has passed over. She is never entirely free from pain. Under proper treatment she was relieved from her attacks of pain, and she has been able to continue her work with properly constructed shoes.

CASE II. Woman, age thirty-five, referred to me by the kindness of Dr. Wellington. After tedious confinement the patient found great difficulty in using the left foot on account of extreme pain in the region of the head of the fourth metatarsal. This pain was aggravated by a local pressure and by squeezing the foot, the pressure of any shoe was at times insupport-

able. No swelling or redness could be found upon the foot. Locomotion was impossible at times. Condition had remained the same for about three months, at times patient being slightly better and relapsing again. The patient had been treated by complete rest of the foot for awhile, but the pain had always returned. Anti-neuralgic remedies had been used. Under appropriate treatment the patient recovered and was heard from several years later as having remained entirely well.

The symptoms in the remaining cases are so much the same that relation of the cases is practically a repetition. They can be briefly summarized as follows:

CASE III. Professional nurse, female, age twenty-five. Treatment imperfectly carried out. Eventual improvement. Case watched for four years.

CASE IV. Nurse, age thirty. Treatment imperfect. Patient gradually improved. Case watched for three years.

CASE V. Nursing Sister of Charity, age twenty-three. Treatment thoroughly carried out with satisfactory recovery. Case watched for one year.

CASE VI. Lady, forty years of age, recovery, but needed carefully made shoes for several years. Case watched for three years.

CASE VII. Lady, forty-five years of age, not treated.

CASE VIII. Lady, twenty-five years of age, of delicate health. A satisfactory result, but needed to have her boots carefully made. Case watched for two years.

CASE IX. Female physician, forty years of age. Satisfactory result followed treatment. Case watched for two months.

CASE X. Professional nurse, thirty years of age. Treatment not attempted.

In three instances the symptoms were observed in men, in one, a gentleman of fifty, of sedentary habits. In addition to the ordinary symptoms there was at times a sensation of twitching of the toe. In another, a priest, a man of slight figure. In a third the patient was a lawyer by profession, thirty years of age, but unusually large and heavy. In none of these was treatment carried out and the results are not known.

In the case of a lady of thirty-five, the pain was not located at the head of the fourth metatarsal, but at that of the second metatarsal. The pain was aggravated by pressure on the dorsum of the foot.

In the case of a delicate woman of twenty-five there was for a time, in addition to the usual symptoms, some swelling, apparently due to a tenosynovitis of the tendon of the fourth toe. The patient required the use of a crutch for two months, and later for three months, a Thomas metatarsal shoe (that is, a shoe raised at the middle of the sole in a way similar to that applied ordinarily at the heel, thus avoiding any strain at the metatarsophalangeal joint). The patient eventually recovered. The case was seen one year later and the foot had remained in a satisfactory condition.

The treatment for this affection which has been considered necessary in the majority of cases, by Dr. Morton, is the excision of the head of the fourth metatarsal bone and of such a portion of the shaft as may be necessary to prevent pinching the branches of the external plantar nerve. He reports a number of cases where a cure has been effected in this way. The

<sup>4</sup> *Lancet*, vol. i, 1889, pp. 533, 707; also *New York Medical Record*, Mar. 1, 1890, p. 355.

treatment mentioned by Dr. Pollosson is, as he states, only partially successful, and consists in the wearing of a rubber pad sole of the shoe. In some of the milder cases Dr. Morton has found success by rest, temporarily bandaging the foot so as to steady the metatarsal bone and prevent its rubbing and pinching the nerve, and the subsequent use of properly constructed shoes.

The cases which have fallen under my observation were all but two of the subacute and chronic type, and did not require operative treatment. In two, where the symptoms were fairly severe, the patients were willing to devote much time, including the use of crutches for awhile, for the sake of perfecting a cure by conservative means, and avoiding an operation, and the result was eventually successful, although in one instance several months' treatment was needed.

The treatment which I have employed in all these cases has been directed to prevent any lateral pressure on the foot. Taking it for granted that the irritated condition is, as Dr. Morton describes, due entirely to the irritation of the nerve by the pressure of the head of the metatarsal upon the nerve, and that this condition would be relieved if the patient walked about without shoes or stockings, I have endeavored, as far as was practicable, to reproduce the barefooted condition. In the extremely sensitive state, I have advised people to keep the foot up, and have used simple remedies to relieve the sensitiveness, such as oleate of atropia or oleate of morphia. I have advised them to use locally such measures as would stimulate the circulation, such as the use of hot and cold water alternately, either by plunging or by showering the foot; the inunction of oleate of atropia and the injection of cocaine; these and rest have been employed until the stage of extreme irritability has passed. The patients have then been allowed to walk about readily, using on their feet either crocheted slippers with digitated stockings, or else stockings split so as to prevent crowding at the toes; and, if the patient walks out doors, the use of moccasins or overshoes; so that, as far as possible, the foot may be in precisely the condition it would be if entirely uncovered. In severe cases crutches have been used for a time. After this state of affairs has lasted for a week or so—in some instances a month—shoes are constructed for the patient by a shoemaker who has been carefully instructed that there should be no lateral pressure. A shoe made to carry this idea out must necessarily be an extremely uncomely one. While there should be sufficient pressure over the instep to prevent the foot from sliding forward, and the toes striking the end of the shoe—front of the shoe—the rest of the foot must be very broad and loose, so that there shall be literally no pressure as far as is practicable. With these measures I have been able in a large majority of cases, after three or four weeks' treatment, to prevent any recurrence of pain, and to make the patients able to go about freely. In some instances the patients have entirely recovered; in a few instances the patients require to wear peculiarly constructed shoe; and in one instance a Thomas metatarsal shoe was needed for awhile; and in some instances the benefit has been but temporary as far as complete relief; but the relief has been sufficient to determine the patient that an operation would not be necessary.

One of the males was an extremely large man, so that the amount of pressure upon the foot was great.

In the youngest patient the weight of the person was comparatively slight,—not more than 112 pounds. In one of them the patient had worn pointed shoes and cramped the foot. In others, the boots were no more pointed than is ordinarily seen in women's shoes.

Some difficulty will be met in procuring properly constructed shoes, as not only are the patients themselves sometimes unwilling to wear unsightly shoes continuously, but shoemakers are invariably inclined to shape the last to a conventional rather than an anatomical shaped foot, but by constant supervision it is possible to have a satisfactory shoe made which is not unsightly. The shoe which is to be worn in the first stage of the convalescence should be looser than that required in the later; and after a complete immunity from pressure for some time,—six months or a year,—the patient is able to wear ordinary shoes, or shoes approaching those customarily made. As a rule, thin-soled boots like slippers are not so comfortable in the acute stage of the affection, as the heavier soles, provided the latter are of the proper shape, for the reason that they do not splint the foot, so that it is without any proper brace. If, however, the foot is cramped, the thick sole offers no advantage. A shoe like a Chinese slipper would properly be of the most use, as the sole is unyielding and the front of the boot is broad. In some instances it is advisable to use digitated stockings, which give more freedom to the toes; and it is also possible to spread the toes apart by pieces of felt, in that way giving more room to the heads of the metatarsals.

The treatment of the affection, which though distressing is readily recognized, may be briefly summed as—either an operation, or rest, and the use (for a while at least) of unusually broad-soled shoes. In the severest cases operative interference is necessary unless a good deal of time be given to thorough treatment.

#### PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

BY HAROLD C. ERNST, M.D.,  
Instructor in Bacteriology at the Harvard Medical School.  
(Continued from No. 2, page 28.)

Of the cases classified as "surgical," some certainly do not come under the head of tuberculosis, by reason of any settled method of diagnosis that is at present at our command. For convenience sake, they are, however, placed in the class to which we now come, in order to separate them distinctly from the one that follows, and which includes those cases that can only be considered by themselves, and in most of which there was not even a strong clinical suspicion of the existence of tuberculosis. The cases now to be considered, therefore, form Class II.

#### SECTION II.

##### SURGICAL AND LUPUS.—CASES XIII—XXXIV.

CASE 13. Boston. Admitted January 3, 1891. Service of Dr. J. C. Warren. Born in Massachusetts, twenty-seven years old, married, housewife. Family history absolutely negative, as far as tuberculosis or lupus are concerned. Had lupus of the larynx in 1878, and nervous prostration in 1883.

Disease began six years ago, with a small red pap-

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1891.

fect skin. The patient, because of the stiffness of this indurated area, is obliged to walk upon the toe of the left foot. Has had no local treatment for some time, but has been taking some form of patent medicine.

January 1st. Dose, .001 gm. At 6.30 p. m., face was swollen, otherwise was all right. At 9, the face was swollen and hot; oozing from the excoriated parts of the face and mouth was increased. The right eye was partially closed by the swelling. Increased discharge from the thigh. Otherwise improved, but weak, and with diminished appetite next morning.

April 11th. Dose, .012 gm. Treatment was omitted. Thigh shows no crusting, as it is in a quiescent state. Scales are whitish over the face, with active ulcerative spots at the corner of the mouth and corners of the eyes.

*Summary.*—Number of injections, 41; amount of material used, 363.4 mg.; highest dose, 22.8 mg.

May 1st. Condition about the same. A very slight amount of crusting on edges of the patch on the thigh, and also on the face. General condition good. Desires to continue the treatment. Discharged relieved. A gain in weight and a marked improvement in the condition of the affected area on thigh; not so marked upon the face, which seems to be becoming more active.

CASE 15. Boston. Date of admission, October 13, 1890. Service of Dr. Mason. Born in Portugal, twenty-five years old, single, housework. General health fair; irregular menses; well developed; fair strength; good nutrition; poor appetite and poor sleep; skin of a yellowish hue; tongue coated with a thick, pasty, white covering, red edges; heart and circulation negative; temperature 100°; pulse 88; no cough. Troubled with sleeplessness for four weeks. Is constipated.

October 19, 1890. Urine high, acid, 1029, clear, a trace of albumen, some blood, a few vaginal cells, one or two hyaline casts. Abdomen swollen; tympanitic over the upper portion, with dullness in the flanks, and changing with the position. An indistinct fluctuation wave was made out. For four weeks has been troubled with pain and swelling in the abdomen. Ten months ago lifted a heavy tub. Has had pain in the back since which is getting worse. Examination shows slight dullness below the inferior angle of the scapula on the left, and diminished respiration (almost absent). Vocal sounds and fremitus were not obtained. The rest of the chest showed respiration and percussion fair.

January 13, 1891. Physical examination. Bladder contained nineteen ounces. Cervix rather low in the axis of the vagina, fluctuating tumor filling in the right cul-de-sac. After catheterization cervix lower down, and pointed backward. Lateral and posterior cul-de-sacs contain a roughly nodular mass, about the level of the internal os, — a cord-like body, which runs transversely across the surface, — possibly tubercular, apparently adherent to the body, slightly movable, and felt bi-manually. Temperature varied markedly during the past few days.

January 16th. Dose, .0008 gm. General condition poor. No subjective symptoms.

March 12th. Dose, .0042 gm. Patient is undoubtedly improving. Menstruated this week for the first time in months.

March 18th. Temperature has been normal since

the last note. Treatment omitted because the patient is suffering from a very severe attack of measles.

*Summary.*—Number of injections, 23; amount used, 106.8 mg.; highest dose, 10 mg.; highest temperature, 104°, after the fifth injection of three milligrammes. Discharged, relieved.

Up to time of attack of measles, showed a very marked and decided improvement in general condition, together with a gain of nearly ten pounds in weight. The local affection showed no especial alteration.

CASE 16. Boston. Admitted February 11, 1891. Service of Dr. C. B. Porter. Age forty, married, ward-tender. Family history good. Disease commenced five months ago with a swelling of small extent on the right side of the neck, gradually increasing. General health fair; appearance well developed; good strength, nutrition, appetite and sleep; no chills, fever or night sweats; temperature 99°; pulse 90; respiration 24. Right side of the neck shows one gland about the size of a hen's egg, lying on the upper part of the sterno-mastoid. Three smaller glands are to be made out above this, and several below.

February 10th. Dose, .0006 gm. General discomfort in the afternoon. No change in the temperature, or in the glands.

March 7th. Dose, .0072 gm. No result.

March 10th. Discharged.

*Summary.*—Number of injections, 11; amount of material used, 48.9 mg.; highest dose 7.5 mg.; highest temperature, 103°, after the tenth injection of 7.5 mg. Discharged, not relieved. No effect was observed upon the tumors.

CASE 17. Boston. Admitted July 7, 1890. Service of Dr. Bolles. Born in Ireland thirty-nine years ago, single, laborer. Family history good. Had measles when he was six years old. Commenced November, 1889, from a twist of the knee. General health good; general strength fair; nutrition good; somewhat anemic; appetite fair; sleep good; heart and circulation negative; stools negative; abdomen negative. Gave the twist to the knee ten months before entrance, accompanied by swelling of the limb. Was operated on by Dr. Cushing, September, 1890.

On December 2d, slight pain and discharge. On the 13th, there was a sinus on the outer edge of the cicatrix. On the 31st, eats and sleeps well. There was a slight discharge from the outer sinus; the one on the inner side is closed.

January 4th. Dose, .001 gm. Headache; pain in the neck; poor appetite and sleep; slight nausea; increased pain in the knee, and then running up and down the leg; discharge from the right sinus somewhat increased.

March 24th. Dose, .0051 gm. Out in the yard yesterday for the first time in six or seven months.

March 28th. Dose, .0048 gm.

*Summary.*—Number of injections, 23; amount used, 102.5 mg.; highest dose, 7.2 mg.; highest temperature, 103.4°, on the second day after the thirteenth injection of five milligrammes. Discharged, not relieved.

May 1st. Patient has shown marked improvement of the general condition since the omission of the treatment.

CASE 18. Winthrop. Admitted January 6, 1891. Service of Dr. J. C. Warren. Born in Maine, nineteen years old, single. One brother dead, and one dying, of pulmonary tuberculosis. Disease began in March, 1889, with ulcerations on the upper right arm.

General health poor; appearance anemic; strength poor; emaciated; poor appetite; fair sleep; heart and circulation negative; has chills, fever, night sweats; breathing is shallow; slight cough; slight expectoration; has pain in the lesions; urine acid, normal color. 1009, albumen one-eighth of one per cent., pus, blood, vaginal and bladder epithelial cells; abdomen negative. First entered the hospital in September, 1889; nine months before, ulceration appeared on the upper right arm, which was persistent and spreading. Was robust and well grown. Lungs sound; granulating ulcers over the right deltoid, apparently superficial.

January 6, 1891. Has lost twenty pounds of flesh since leaving the hospital, and failed steadily in strength. Has constant cough. Some ulcerations healed, some appeared and some old ones reopened. Examination showed that under the left axilla there is a fluctuating tumor, of the size of a walnut, with a number of small ulcerated surfaces over the whole upper half of the chest, with the skin about them red and infiltrated. Slight discharge of purulent fluid. In the left apex, diminished respiration, coarse and fine moist râles, extending to below the third rib.

January 7th. Dose, .001 gm. Fever reaction. No increase of cough or expectoration. The abscess under the left arm is enlarged and softer. The discharge slightly increased.

February 21st. It being evident that the treatment could not save the patient, it was deemed advisable for her to go home while it was possible to transport her. Discharged. Died in about three weeks.

*Summary.*—Number of injections, 10; amount used, 27.7 mg.; highest dose, 4.8 mg.; highest temperature, 104.4°, after the seventh injection of four milligrammes. Discharged, not relieved.

March 10th. Patient died of exhaustion about two weeks after leaving the hospital. No autopsy was obtained. Treatment was begun at all only as a desperate chance, and by request.

CASE 19. Athol. Admitted December 31, 1890. Service of Dr. J. C. Warren. Nineteen years old, single, clerk. No family history of tuberculosis. Disease began with pneumonia nine years ago. General health good; fair strength; good nutrition; good appetite; heart and circulation negative; has a slight pain in the chest; abdomen negative. Had an attack of pneumonia, lasting five months, nine years ago. Pus was drawn off with a needle from the right lung. Was well until three years ago, when an abscess formed in the right side, which was lanced, and there has been a constant discharge of pus since then.

Examination shows a well-nourished boy, in a good state of health. In the sixth interspace of the scapular line is a cicatrix, evidently the mark of a previous opening. A spot over the seventh rib, and outside the mamillary line is the opening of a sinus upward for about three inches. It does not appear to communicate with any cavity, nor extend from side to side for any distance. Percussion note over the right chest is vesiculo-tympanic; respiratory murmur almost entirely absent. The sinus syringed out, and a dry dressing applied.

January 3d. Dose .001 gm. No reaction.

February 24th. Operation by Dr. Warren. Ether. Two and one-half to three inches of the rib were exposed, close to the costal cartilages. The soft granulations removed with a spoon; a pocket of foul pus in

the posterior part of the chest; two pieces of drainage-tube, each two inches long, found and removed (very foul and nearly disorganized). Cavity washed out.

March 7th. Dose, .0078 gm. No result. Weight 115 pounds. Sent to the Convalescents' Home.

April 20th. The report is that the general condition is much improved. Feels as well as he ever did. Discharge very much diminished; thin and no odor. Lung resonant about the sinns.

*Summary.*—Number of injections, 18; amount used, 144.8 mg.; highest dose, 21.6 mg.; highest temperature, 102.6°, after the fifth injection of three milligrammes. Discharged, not relieved (by the treatment).

CASE 20. Roxbury. Admitted March 10, 1891. Service of Dr. F. C. Shattuck. Born in Boston, thirty-six years old, married, physician. Mother's sister died of consumption. No other cases on either side. Has five brothers and sisters living and well. Has had measles and chicken-pox. Disease began, two years ago, with a sore spot in the trachea, after having had a cold. Glands above the left clavicle are enlarged and tender. Has febrile attacks about every four weeks, then a normal temperature, and repeats. General health good; no hæmorrhages; is of a dusky appearance; fair strength; good nutrition, appetite and sleep; no chills; periodical fever; temperature 100°; pulse 115; respiration 24; breathing slightly interfered with; no cough except a dry hack; no expectoration; no bacilli have ever been found in the sputum; has pain only at the time of the febrile attacks; no nausea; no vomiting; urine pale, 1010, acid, no albumen; abdomen negative. There is distinct swelling of the glands about the region of the right clavicle at the neck. Other examinations negative. Hæmoglobin sixty-five per cent., according to outside examinations. The special peculiarities of the case are the repeated febrile attacks, attended with pain and swelling of the affected glands, occurring at repeated intervals. Has moderate dyspnoea during the attack. Is just recovering from one at the time of entrance. Treatment at patient's request.

March 11th. Dose, .0006 gm. General condition fair; good appetite; poor sleep; increased cough; increased pain over the right chest. Temperature rose a little earlier in the day than usual.

March 23d. Dose, .0072 gm. General malaise increased; increased cough; increased pain in the glands. Patient was discharged because further treatment seemed hopeless, and because of the result in Case 32.

*Summary.*—Number of injections, 7; amount used, 27 mg.; highest dose, 7.2 mg.; highest temperature, 101.8°, after the fourth injection of 4.8 mg.

April 19th. About a week after leaving hospital, patient had high temperature, much increased swelling of cervical glands, with pain; dyspnoea; loss of right radial pulse. In three days, temperature sank; and the enlarged glands have almost completely disappeared. General condition much improved. Discharged, relieved. The relief in this case is present, but not explicable.

(To be continued.)

In reply to an inquiry from the Marine-Hospital Bureau, relative to newspaper reports of cases of yellow fever at Brunswick, Ga., a telegram was received stating that there has not been even a suspicious case.

THE CLINICAL COURSE AND THE PRINCIPLES OF TREATMENT OF CHRONIC ANKLE-JOINT DISEASE IN CHILDHOOD.<sup>1</sup>

BY CHARLES L. SCUDDER, M.D.,

Assistant in Clinical Surgery, Harvard Medical School, Boston, Mass.

TUBERCULAR disease of the ankle-joint in children manifests itself by a sequence of unique signs and symptoms.

The following report of a case is made in much detail, for it presents an almost complete picture of the course of this not very uncommon affection. Therefore, it affords an admirable opportunity for the presentation of the principles upon which is based the treatment of chronic ankle-joint disease in childhood.

E. B., four years old, one of six children, had always been well. Her family is of English descent, giving no tubercular history, and generally in good health. In October, 1888, she received a slight injury to the left ankle. Subsequent to the traumatism, the ankle-joint was slightly swollen and puffy, particularly at its outer side. Upon beginning walking in the morning the ankle was stiff. After walking the child became tired and was a little lame. There was no pain, neither was there tenderness felt.

The mother tells me that in February, 1889, a starched bandage was applied to the ankle and allowed to remain a short time. In June, 1889, a plaster bandage was used, and was worn for fully two months. Upon its removal the child walked very stiffly. Then liniments and a silk bandage were employed. The child continued lame, and the swelling about the ankle persisted.

In February, 1890, I saw the patient for the first time. Upon examination, I found a child rather pale, but well nourished and well developed, who walked with a decided left ankle-joint limp. A fullness existed behind and on either side of the malleoli, greatest below the inner malleolus. Fluctuation is indistinctly present over this swelling, and elsewhere about the joint there is an elastic feel. The surface temperature is slightly elevated. Motion is present at the joint, but within the extremes of flexion and extension it is limited by muscular spasm. Upon forced passive motion the child cries from pain. The left calf is one inch smaller than the right. The left foot is three-quarters of an inch shorter than the right foot. The left ankle measured over the heel and swelling one inch more than did the right ankle. The left tibia is shorter than the right, and there is no apparent difference in the two femora.

Pain is present from slight jarring of the foot, and the child refuses to walk. The foot and ankle are carefully guarded from accidental injury. There is no history of especial pain at night.

A posterior wire splint from the toes to above the knee, together with a Thomas knee and ankle splint, were applied. A bandage was put on from the toes to the knee, affording even compression. A high shoe on the well foot and crutches completed the outfit. The patient was encouraged to go out of doors. A general tonic was given. At the end of six weeks the condition was not so good. There was loss of appetite; a pale appearance of the face; the local pain was more severe; the swelling about the joint was greater. The disease was progressing, and that rapidly.

Therefore, in April, 1890, one year ago, under antiseptic precautions, I operated by the two lateral incisions, removing all periarticular gelatinous material, and also removing the diseased astragalus entire, with the cuboid and one-third of the os calcis. I curetted very thoroughly considerable of the lower epiphysis of the tibia, until good hard bone could be felt on all sides. Thorough bichloride irrigation was employed before the removal of the Esmarch. The cavity formed was packed with corrosive sublimate gauze. A posterior wire and side splints were applied, with even pressure. The first dressing was done on the tenth day, and all went well. The patient was allowed to be about with the Thomas splint soon after the operation. Six months later she was walking on the foot, having been let down from the support of the splint tentatively.

The present condition of the joint, one year after the operation and six months since first walking on the foot is as follows: The wounds are healed. There is no tenderness. The arc of motion at the left ankle is between 35° and 40°; at the right ankle, 66°. The left calf is three-quarters to one inch smaller than the right calf. The left tibia is three-quarters inch shorter than the right tibia. The left foot is seven-eighths inch shorter than the right foot. There is a limp in walking, which gradually is becoming less noticeable. The general health is excellent.

The duration of the disease, from the first noticeable symptoms to the time of the healing of the operative wounds, was, therefore, about two years. The usefulness of the foot is all that can be desired.

How shall the initial symptoms be interpreted? The disease probably began before the slight injury in 1888. Traumatism plays a very small part in the etiology of chronic joint disease, and particularly in the ankle-joint. At first the trouble was unnoticed, and then swelling appeared, unaccompanied by pain or lameness. If the joint at this stage could have been looked at there would have probably been found a synovial membrane thickened, having a gelatinous, grayish appearance, studded here and there with milary nodules corresponding to tubercles. And a granulation tissue would have been seen projecting fungus-like from the altered synovial membrane into the joint space. The synovial fluid would have been found altered in appearance. Pathological evidence is yet to be furnished, which will demonstrate the existence of a *primary* tubercular synovitis. Clinically these cases exist as a chronic synovitis, with the strong presumption that they are either primarily tubercular or secondarily so. There was no pain because the synovial membrane, the only tissue involved in the disease, contains few nerve filaments. The onset of the disease was insidious, and the progress slow. This very progressiveness, however, is characteristic of the lesion.

The symptoms of chronic *synovial* disease are, therefore, a gradual onset; change in the joint outline; an elastic feel about the joint; a normal use of the joint; the absence of a marked limp, of pain and of muscular spasm; and, finally, the absence of remissions. The disease is continuously progressive.

What are the indications for the treatment of a beginning chronic synovitis?

In this case immobilization was attempted by means of stiff bandages, and traumatism was permitted, for, with the bandage on, the child walked about. This

<sup>1</sup> Read at the meeting of the Surgical Section of the Suffolk District Medical Society, April 1st, 1891.

treatment was entirely wrong, and worse than useless, as the subsequent course of the disease proved. Nature indicates the principles of treatment very clearly. The joint is allowed to move painlessly, therefore does not immobilize. And repeated traumatism, received in walking, caused in the ankle-joint a tired feeling and stiffness, therefore modify or prevent trauma, either by walking less or by completely protecting the joint, or by removing the pressure of the body-weight to the perineal band of a suitable apparatus. We should then seek in the treatment of chronic synovitis to allow joint motion without permitting the trauma of locomotion.

After the evidences of synovial disease were well established, we find that new and remarkable symptoms developed. As the granulation tissue associated with the tubercular process extends and invades the cartilage and the bony tissue beyond, and the purulent and cheesy products accumulate, the swelling increases rapidly, and the joint becomes extremely sensitive. Then appears muscular spasm; and muscular and bone atrophy become prominent.

The sensitiveness is due to the involvement of the bony epiphysis, which is well supplied with nerves, and it is due also to the distension of the articular and periarticular tissues with the rapidly accumulating inflammatory products.

The muscular spasm is Nature's method of splinting the joint and preventing the harsh opposition of two inflamed bony surfaces. Muscular spasm always accompanies an osteitis of the joints, and its detection at an early stage of the disease is of the highest importance, and demands the nicest judgment. It is of reflex origin, purely involuntary, and is overcome only by very great force, complete anaesthesia or the proper treatment of the disease. It is the evidence par-excellence of chronic osteitis.

The muscular atrophy is greater than that associated with simple disuse of the limb, and its cause is to be discovered in some nervous lesion. The bone atrophy is always associated with any interference with the development of the epiphysis, and it is a fact, I believe first emphasized by Shaffer,<sup>2</sup> of New York, that there is a direct relation existing between the location of the inflammation and the amount and character of the muscular spasm, the muscular atrophy, and the bone atrophy.

The presence in this case of marked atrophy in the length of the foot, together with the position of the swelling, led me to locate the bone lesion in the astragalus, and upon measuring the tibia and finding it likewise greatly shorter than the opposite bone, I suppose the disease to have invaded its lower epiphysis. The result of the operation confirmed the observation as to the seat of the lesion.

How strongly contrasted are the pictures here presented of the two great classes of chronic ankle disease, the synovial and the osteitic! On the one hand is the lowly organized non-sensitive synovial membrane, involved in the slowly progressing tubercular inflammatory process. The purely objective signs of local swelling and elasticity in the part and a slight tired feeling upon exertion, silently afford evidence of the disease. All else is negative. On the other hand, the more sensitive bone-tissue being involved, the symptoms are both objective and subjective, and greatly intensified. There is increased swelling, in-

creasing disability of the joint function, walking becomes difficult and eventually is not even attempted. There is present the involuntary muscular spasm, checking undue mobility of the inflamed parts. Then appear muscular and bony atrophy. Pain is often present independent of movement.

Occasionally the osteitic cry at night is heard, resembling that so commonly associated with chronic disease of the hip-joint.

The indications for the treatment of chronic osteitis of the ankle-joint then are evident. The muscular spasm is often so great as to hold the joint perfectly rigid, as if firmly ankylosed. Here is indicated absolute immobility, the first principle of treatment. The characteristic limp, which interpreted means a disinclination to use the joint, points to the prevention of all traumatism as the remaining principle of treatment.

The application of these principles necessitates the use of some form of apparatus, which requires in each class of cases the nicest judgment in design and the greatest care in adaptation, and it must be modified from time to time to meet special requirements as the case progresses. "The appliance is only a tool which is capable of being manipulated to produce certain results. . . . Here, as everywhere in strictly orthopedic work, it is a question of method, not means; principles, not rules; men, not machines."

The proper adaptation of apparatus to chronic joint disease just described; the correction of any malposition occurring in the course of the disease; the careful attention to the general health; the occasional opening of an abscess,—these procedures constitute the expectant method of treatment.

It is true that in a majority of cases of chronic ankle-joint disease the mechanical treatment, based upon established principles, is demanded; and that, if perseveringly and intelligently carried out, it will result in a satisfactory termination of the disease. It is, however, a clinical fact, that tuberculosis of the ankle-joint, whether of primary synovial or osteitic origin, at times appears most malignant. The parts seem to go all to pieces, in spite of these expectant methods, as in the case reported. The attack by the bacilli is most virulent. Tissue is quickly destroyed,—great abscesses form in consequence. The general health fails.

What, then, are the indications for treatment in this class of cases? They are as plain, and based on as sound principles, as any in the field of either mechanical or operative surgery. Nature is attempting, in her slow and tedious fashion, to get rid of the diseased part, which at first is a purely local affection. The indication then is, for a complete excision of this local disease. The surgeon, by excision, merely interprets Nature's need and assists her.

An excision may be done either at the outset of the disease or as a last resort, or at the first appearance of malignancy. The results of the expectant methods in the early stages of the disease are too good to justify operative interference at that time. The best results are not obtained when an excision is done as a last resort, late in the course of the disease. It is the surgeon's duty, who assumes the responsibility of the treatment of chronic joint disease, to be so familiar with the details of his cases that he may detect the first evidences of malignancy; and when they remain unchecked by proper mechanical treatment, then, and only then,

<sup>2</sup> *Loc. cit.* on Ankle Dis. *Annals of Surgery*, 1882.

judging from all the evidence that can be obtained, is an operation justifiable.

The only possible exception to the above rule will occur in those children of poor parents who cannot give the time and the proper care to expectant methods. In these children an earlier operation is justifiable.

In determining the evidences of malignancy or need for operative interference there are many factors to be considered in each individual case. These are: The age of the patient; the duration of the disease; the previous treatment; the hereditary history; the present appearance of the part; the general condition of the patient; the circumstances of the patient. The importance of each of these factors has been discussed elsewhere, and need not be dwelt upon here.<sup>1</sup>

From a study of the cases of ankle-joint disease operated upon at the Boston Children's Hospital during the twenty years between 1869 and 1889, and in which the end results are known, the following observations have seemed clearly warranted.<sup>1</sup> Primary amputation in children and young adults is never justifiable for chronic ankle-joint disease: an aseptic complete excision of the diseased bone is a safe procedure; a partial operation is comparatively of no value; gouging and the burr drill are blind methods, and almost worse than useless; the time of the after-treatment is greatly diminished; the general health improves rapidly after excision; profuse suppuration and its attendant dangers are immediately checked; the danger from tubercular and septic infection is diminished; the extent of the disease does not contraindicate an operation for its removal; the result as to usefulness in all cases has been good.

In conclusion: The case reported illustrates the two great classes of ankle-joint disease, the synovial and the osteitic. From it the principles of treatment for each class have been deduced. This case has also demonstrated (1) the failure of improper treatment at the initial stage; (2) the failure of proper mechanical treatment when too late to be of benefit; and (3) the success of operative measures, the indications for which have been given.

## Reports of Societies.

### SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

GEORGE H. MONKS, M.D., SECRETARY.

REGULAR MEETING, Wednesday, April 1, 1891, Dr. A. T. CABOT in the chair.

Dr. O. K. NEWELL read a paper on

THE TREATMENT OF URETHRAL STRICTURE, AND SHOWED A NEW DIVULSOR FOR RAPID DILATATION.

Dr. H. W. CUSHING: Did I understand you to say that stricture of the urethra was incurable?

Dr. NEWELL: Yes.

Dr. CUSHING: Do the remarks you have just made apply to strictures of the urethra, regardless of their site and origin?

Dr. NEWELL: That statement applies to every stricture where plastic lymph has become organized, and true cicatricial tissue has formed.

Dr. CUSHING: I understand that the method you

would advocate would be gradual dilatation except in a few extreme cases?

Dr. NEWELL: Yes. I hold stricture of the urethra incurable, just as esophageal or rectal stricture. The only way of maintaining a good lumen is by watching and passing some sound or divulsor. A good many inflammatory strictures pass away, and I think a urethral stricture might be cured by means of a plastic operation, but one formed by the organization of exuded lymph I do not believe is curable.

Dr. CUSHING: That statement differs from the opinions of other specialists. Without referring to recorded statistics in my personal observation I have seen strictures which have been practically cured by urethrotomy. These patients return from time to time for observation, but apparently very little change has taken place in their urethra from year to year. I can recall one or two instances which I have had under observation at the Genito-Urinary Department of the Boston Dispensary for several years. These cases were operated on by Drs. Watson and Tilden in 1883 I think. I remember seeing one of these cases last year, and having the opportunity of examining it, and as far as could be determined from our previous records there has been no special change. The patient is well.

The system of gradual dilatation is I think a very valuable one, but I think I should hesitate in going quite so far as Dr. Newell does in saying that the treatment of strictures should be limited almost entirely to that method. In certain cases (of course I do not refer to those cases where there is a marked narrowing of the urethra, apparently due to subacute inflammation or edema which can be relieved no doubt by gradual dilatation), there exists such a sensitive condition that any attempt at manipulation in the usual way, by gradual dilatation, is followed by quite serious symptoms; and in those cases it has been found, in the experience of some surgeons, and also my own, that such patients not infrequently can be submitted to a cutting operation, and a favorable result rapidly obtained without any of that unpleasant and sometimes dangerous reaction which accompanies occasionally gradual dilatation, and the continued irritation of passing instruments according to that method.

Another thing which interested me was Dr. Newell's statement in regard to the results following division. I should like to inquire if Dr. Newell can give me any information as to what takes place when this method is employed? If there have been any post-mortem observations? I think you made some experiments on the cadaver. My experience with cutting operations, both internal and external, has been much more satisfactory than Dr. Newell's statement would lead me to expect.

I think a more satisfactory classification of the treatment employed in these cases would be according to the site and character of the stricture; some of the deeper strictures being very satisfactorily treated by the method of external urethrotomy; others, situated more anteriorly, by means of internal operative manipulation, preferably the "Otis" method.

Dr. G. W. ALLEN: I have read, with a good deal of interest, about Oberlander's treatment of stricture which is a modification of division or rapid dilatation by means of an instrument with spreading blades, which, by means of a screw, are opened to any extent, on the principle of Otis's urethrametre.

<sup>1</sup> Boston Med. and Surg. Journal, January 30 and February 6, 1890.

It is my impression that the class of cases in which he most uses this treatment is that of strictures of large calibre in the anterior urethra, and according to my experience the commonest site of stricture is the peno-scrotal angle, or within an inch or a little over anterior to that point. The peculiarity of these strictures is that they are generally associated with or perhaps caused by an inflammation of the lacunae, constituting a glandular or periglandular urethritis.

These glands, when inflamed, may be seen through the endoscope as minute punctiform depressions scattered along the anterior urethra, but most numerous in the vicinity of the peno-scrotal angle where they are apt to occur in groups, generally on the roof or sides of the urethra, and are, as a rule, associated with a rigid appearance of the mucous membrane. At such a spot the olive-pointed bougie will invariably show the presence of stricture.

I think this condition has more to do with keeping up gleet than any other one thing. The matter of stricture is of secondary importance and it makes very little difference how large the stricture is; it is the condition of the mucous membrane which keeps the discharge going. I have seen a case where the calibre of the stricture was thirty-eight, but the trouble from it was as great as if it had been twenty sizes smaller. Oberlander's idea is to dilate this point at successive sittings, two or three sizes at a time. The result is to split open these little glands, after which applications of nitrate of silver are made.

DR. A. T. CABOT said that he was surprised to hear Dr. Newell advise the daily use of bougies for the gradual dilatation of strictures. In his experience such a frequent use of instruments through the urethra acted rather as an irritation, and excited the stricture to contraction rather than accomplished its dilatation. In moderately close strictures he had often found it impossible to pass so large a bougie on the second day as he had done on the previous day. This seemed to be due to the swelling of the mucus membrane through the stricture caused by the irritation of the instrument.

In answer to the question of Dr. Cushing as to the result of division, he would say that it had happened to him to see autopsies in two cases where he had divided the urethra. One of these patients died of disease of the suprarenal capsules, and the other one of suppuration around the gall-bladder. The division had been done about three weeks before the death in each case. In both of them the stricture had been a rather narrow one, admitting only a filiform bougie, but had yielded readily to division. In both, the post-mortem appearance was of a perfectly smooth mucous membrane at the site of the stricture. There was no evidence of laceration such as we are told always follows division. It was certainly in each case as good a result as we could expect from any method of treatment whatever.

The kind of stricture in which an invagination may take place by efforts at division, is the very tough cartilaginous stricture which is ordinarily met with in the penile portion of the urethra. The speaker said that he had known of one such case where the divulsor tore away the urethra at the point of the stricture, and pushed it into that portion of the canal posteriorly. He would prefer to treat a stricture of this sort by internal urethrotomy. If, however, it was deemed wise to divide such a stricture, he should think that

the little advance blade of Dr. Newell's instrument might, by insinuating itself through the stricture, make such division easier.

He said that practically, he had never met with a case, where he thought division a proper operation, in which the Bigelow divulsor did not hug the shaft closely enough to insert itself within the stricture and readily divide it. The instrument with which the invagination used to take place was the much more blunt-pointed divulsor of Voilemier.

In regard to Dr. Newell's statement of belief that external urethrotomy should only be used in impermeable strictures, he would say, that that was a point on which there might be very great differences of opinion. Among a large number of the best practitioners in this branch of surgery, in the country, for instance, it is the opinion that all deep strictures when they are tolerably tight and resistant, and do not yield readily to gradual dilatation, should be treated by external urethrotomy. This opinion is based upon the belief that by external urethrotomy, and providing an adequate drainage for the bladder, there is less danger of septic absorption and of consequent serious results than after division or internal urethrotomy. Also by external urethrotomy, the stricture can be divided more intelligently, and even in appropriate cases the strictured area can be completely removed, and the ends of the urethra brought together where the separation is not too great, or a mucous membrane from some other part can be introduced to fill the gap. Probably in this question, like so many others where opposite views are held by intelligent men, the truth lies somewhere between the extreme views, and it is best to select for each case the operation suitable for that case. If the stricture is soft and readily divided, that is probably the best operation; whereas, if it is more resistant, and the division would seem likely to cause considerable laceration of the urethra, the external urethrotomy should probably be the operation of choice.

DR. NEWELL: In the first place, although I have tried to construct a divulsor, yet I do not believe in division except where you are obliged to do it. I believe the best treatment is gradual dilatation, with the stricture in whatever part of the canal. I wish some one had criticised the intermediary cases where you make a primary division in order to get ahead faster with a very small stricture.

In regard to Dr. Cushing's question in reference to cure, and just what happens, I base my opinion largely on the authority of a mutual friend of ours, Professor Dittel, of Vienna. He wrote the volume on "Stricture" in the *Deutsche Chirurgie*. He has collected an immense amount of material, and has a splendid atlas on the subject, with specimens and water-color views by Heintzmann. I speak of that so that we can answer the question as to what happens in division, in contradistinction to what we know to happen in internal urethrotomy. A stricture is usually a uniform condition around the urethral canal, and you don't have a local single thickening of the canal. It is on section of the strictured urethra very rarely that you find a laterally thickened portion with organized cicatrix. The disease is pretty evenly disseminated, so that you have around the urethra an organized tube of callous of varying lengths. This when rapidly stretched with the divulsor is ruptured in lines radiating pretty evenly throughout its circumference. This is in contradis-

tion to urethrotomy where you cut in one direction. In regard to what Dr. Cahot said as to the size of strictures, and the frequency with which instruments are passed, I think that is perfectly true; and I stated in my paper that I always advised patients that the best interval is every other day. Where the irritation is slight, I find every other day is the best period of frequency. Reginald Harrison has spoken of this matter of "reaction." I think this is something that is disappearing from urethral surgery. It is seldom seen nowadays. Patients seven or eight years ago died from urethral fever, etc., but the danger at present has been much diminished. In Professor Dittle's work, which was published about six years ago, he gives a long list of accidents from this cause among the earlier cases.

I think one danger of external urethrotomy is the liability that the fistula may be permanent. In a recent discussion in New York there has been a great objection to internal urethrotomy. One man remarked that he had got tired of having patients come to him with their boots full of blood.

As to the cure and the time, Dr. Cushing mentions cases of eight years ago. It is not a matter of three or eight years with a stricture; it may be a matter of ten, twenty or thirty years, but in time it will come back if unattended to.

DR. E. H. BRADFORD read a paper on

#### A PAINFUL AFFECTION OF THE FOOT.<sup>1</sup>

DR. CUSHING: Does this ever occur between any other metatarsal bones than the fourth and fifth?

DR. BRADFORD: Dr. Morton saw one between the second and third. He has seen one case at the third, and I have seen one at the third.

DR. CUSHING: I have personally treated but one case which might be included among those described by Dr. Morton. In that patient, a girl of fourteen, the neuralgic pains were not so marked as Dr. Bradford has portrayed, nor did they extend up the leg. The tender spot was on the dorsum of the foot, and in the second metatarsal space. The patient was readily relieved by systematic and careful bandaging with flannel. If the pathology of this affection is as stated by Dr. Bradford, it would lead me to doubt my diagnosis, since by bandaging the tissues were compressed as well as immobilized, and one would suppose that such pressure (as here described) on a sensitive nerve would cause pain rather than relieve it.

DR. BRADFORD: Dr. Morton mentions the use of a bandage in that it steadies it.

DR. J. J. MINOT: I should like to ask whether the same thing might not be brought about by using an internal sole, with a big shoe, and then cutting holes through the soles to relieve the pressure and bringing the pressure differently.

DR. BRADFORD: I do not think that that would. That is useful for a different condition of the foot.

DR. C. L. SCUDDER read a paper entitled

#### THE CLINICAL COURSE AND TREATMENT OF CHRONIC ANKLE-JOINT DISEASE IN CHILDHOOD.<sup>2</sup>

DR. BRADFORD: I think there is nothing to be added to this excellent paper. I am very glad he has emphasized one fact that I think is often overlooked, namely, that in osteitis of the ankle-joint, encasing the foot in plaster-of-Paris and allowing the patient to

walk without splint or crutches is careless treatment. When you have a diseased astragalus with a tubercular focus in the middle of it, you cannot allow walking with safety, unless crutches or a splint are used, and this is true although walking may not be painful; where there is a pure tubercular synovitis without disease of the bone, the danger is less. In regard to operation, I think the tendency of surgery is expressed by some writer, that we tend toward greater boldness in the ankle, greater boldness in the knee, and more conservatism in the hip.

DR. BRADFORD, then showed

#### A FIBROMA OF THE UTERUS REMOVED BY HYSTERECTOMY.

During the operation the bladder was accidentally wounded. It was sewn by Dr. Watson and held perfectly, as was shown at autopsy three weeks later, death occurring from sepsis.

DR. BRADFORD also showed a specimen of

#### AN APPENDIX REMOVED DURING THE INTERVAL OF THE ATTACKS,

which was interesting, as these cases were not common. The appendix was removed after the third attack. The patient made an excellent recovery.

#### MASSACHUSETTS MEDICAL SOCIETY. THE ONE HUNDRED AND TENTH ANNUAL MEETING.

BOSTON, JUNE 9 AND 10, 1891.

#### SECTION IN SURGERY.

(Continued from No. 2, page 38.)

DR. JOHN HOMANS: The treatment of inflammation of the appendix has been actively discussed for about five years. The diagnosis has been pretty well settled, and any physician up to the ordinary standard of to-day ought to be able to make it. I will not waste time talking about this part of the subject we are considering.

Notwithstanding all this discussion until the subject has become almost trite and hackneyed, the practical recognition of cases that would be fatal if left to themselves and of those that would recover without surgical aid, is as difficult as ever. In my own practice, when I operate I am sure that I am right; but when I do not, I am not sure that operation ought not to have been done. The condition of the abdomen both internally and in its walls, after laparotomy for appendicitis, is not always satisfactory, and some of the recoveries might almost as well have died. I have had under my care, for the last four months, a man successfully operated upon, nine months ago, who has chronic discharge from two sinuses, the seat of former drainage-tubes. Another case of long but perhaps perfect convalescence, lasting more than four months, and in which the appendix was removed, has a hernia.

The possibility of the supervention of chronic supuration, or of hernia, ought not to prevent us from operating on a case of appendicitis; but how are we to distinguish those cases requiring operation from those that will recover without it? I confess that, in a doubtful case, I am guided largely by rational symptoms.

Again, those cases have done the best, in my experience, where a well-defined abscess has formed at the

<sup>1</sup> See page 62 of the Journal.

<sup>2</sup> See page 59 of the Journal.

end of ten days or even of several weeks. So, I prefer, if I can, to wait until such an abscess has formed, if possible. But how are we to know it is going to form, and that the patient will not die of septæmæmia or general peritonitis, before we have the appendix shut off in an abscess? I operated once within thirty-six hours of the first symptoms, on a strong, healthy boy of twelve. I found the abdominal cavity to contain opaque serum, floating freely and not encysted. I did not find the appendix; but at the autopsy, five days later, Dr. Fitz found it gangrenous in the rectal fossa by the side of the rectum, and covered by the gangrenous bowel. There was general peritonitis and much pus. I believe this case was necessarily fatal from the start, and so are some others; but my early operation was of no use.

Lately I saw a case on the fifth day: a boy, nine years old, a patient in Dr. W. L. Richardson's ward in the Massachusetts General Hospital. I judged it best to delay operation a few days, and I think the result justified my action. Three days later the abscess was opened by Dr. Warren for me, in my absence, and the boy is doing well. The appendix perforated but swollen, was removed.

I have under my care at present a case not requiring operation, I think. A lady has been comfortably ill for two weeks. There is a distinct tumor in the right iliac fossa. The tenderness is gradually subsiding. Now, if she gets able to be about and attend to her duties without inconvenience or pain, in short is well, she will be better off than if she goes about a year waiting for an abscess to close — and these abdominal abscesses seldom do close — or a ligature to come away, or a hernia to be cured, or with pains from adhesions. I have stated all these drawbacks, not because I wish to discourage laparotomy for appendicitis, for I am a firm believer in it, and if any one will look over my contributions to the *Boston Medical and Surgical Journal*, he will find many cases of appendicitis operated on by me; but I want to learn to distinguish between those cases which demand and those which negative operation.

Now, if successive attacks of appendicitis cause life to be of little value from apprehension or interruption, I would recommend an operation for removal of the appendix. Such a case I have lately treated; and I found the appendix wrapped up in a piece of thickened and gangrenous omentum, from which, and from the bowel, it was separated by a patient dissection, and was removed, close to its base. A piece of omentum, more or less gangrenous, as thick as my finger, and about two inches square, was also removed. This man recovered. Perhaps he would have done better if he had been operated upon in his first attack, but I am satisfied with the result. Gangrenous appendicitis demands operation. How are we to distinguish it from catarrhal inflammation? I think we must be guided in a great measure by the rational symptoms. If a day or two after the first onset vomiting ceases, the countenance becomes bright, the temperature falls below 100°, and the pulse to about 80, and the abdomen is soft and not tense, I think we may expect a favorable issue, with a convalescence tardy often, and tedious, but still pretty sure. On the other hand, a tense abdomen, great mental anxiety, a rising temperature and pulse, with inability to take food, and increased tenderness in the iliac region, especially with a protrusion into the rectum, urge im-

mediately operative interference, and removal of the appendix also, if it is easily found.

The varieties of appendicitis may be classically called four:

(1) One in which the appendix is perforated, and perhaps the cæcum also, and general peritonitis is at once set up. This class of cases is generally fatal, with or without operation.

(2) Another variety has perforation of the appendix, with limited peritonitis, soon shut off in an abscess of varying size, but generally rather large and forming a well-defined tumor, often quite prominent. This class demands operation and drainage, and is generally cured.

(3) A third variety has the appendix swollen and cedematous, but unperforated; and yet the symptoms are severe, and there is great anxiety and often distension. The tumor here is ill defined and small, but there is considerable tenderness, with high temperature, pulse and abdominal distension. With no improvement in three or four days, laparotomy, and removal of the appendix, if easily found, is proper.

(4) The fourth variety has a sharp pain at first, soon subsiding. Perhaps one attack of vomiting, a tenderness on pressure, and a swelling in the right iliac region, and without any tumor in the rectum. These cases resume an almost normal temperature and pulse in a few days, and though the convalescence often lasts from four to five weeks, yet health is finally restored. The liability to subsequent attacks, however, is problematical, but operation in the initial attack is improper.

The diagnosis of appendicitis is one easily made. The treatment by operation consists in making an incision about three inches long, over the most prominent part of the swelling. When this is not well defined, the centre of the incision should be at a point about two inches from the anterior spine of the ilium, in a line drawn toward the other iliac spine. If there is difficulty in finding the appendix, you will be guided to it by the longitudinal bands on the cæcum, all of which lead invariably to the base of the appendix, as was pointed out to me about two years ago by Dr. Whitney, the Curator of the Warren Museum. In this operation the appendix should be removed if it is easily found, and its base should be tied, and its mucous surface turned in by a suture. Except in the cedematous catarrhal cases, without much, if any, suppuration, drainage with one or two tubes of rubber or glass, should be practised, and the cavity should be well irrigated. The edge of the wound, the suture-holes, and the interior of the abscess slough more or less in severe purulent cases, and although without drainage, the necrosed tissue and pus generally break through externally rather than internally, yet I think drainage is safer.

The convalescence in all cases, whether operated on or not, is apt to be long, and I do not think it any quicker in those cases where the appendix is removed than in those where it is not found. As I said some three years ago, I think the treatment of appendicitis is the most important practical question in surgery at the present time.

DR. C. B. PORTER: It seems to me that the subject of appendicitis, or the cases of that disease rather, can be divided in a general way into three different classes. The first and most important is what has been called the fulminating type of appendicitis, in which all the

symptoms are in great excess over the other two forms, and in which, without early interference, death is sure to follow. The second is the acute variety, in which the symptoms enter in with nausea, vomiting, pain referred to different places, generally to the umbilicus in the first place, and then to the right iliac fossa, and then to some other portion of the abdomen, this being easily explained by those who recognize the great variety of the positions of the appendix in the different cases. Then the third class, which is subacute, and in which the symptoms are not so well marked, and in which they progress much more slowly, and in the majority of cases recover.

Your chairman invited me to speak to-day more especially upon the third class, as I have defined the three; and those are the cases which give the recurrent attacks, or, in other words, the constant and repeated occurrence of pain, nausea, vomiting and invaliding, often, in bed. The whole subject has interested me, as other active surgeons, for a number of years; but some three years ago this subject especially was brought to my mind from the fact that Dr. Hodgdon, of Arlington, brought me the case of a young man who had an attack nearly every month, which put him in bed, and he was in such a condition that he really was unwilling to absent himself from home for a night, for fear he would have an attack and be away from his home surroundings and from his physician. Going over the case very carefully, and having already looked up the literature of the subject before that, and seeing what had been recommended by Treeves and others, Dr. Treeves being the first man who recommended the excision, I proposed that he talk the matter over at home and decide whether he would submit to an operation. They selected the operation. That was done in the remission between the attacks. That was the first case which I operated upon, and it was more than two years ago. The appendix was found enlarged, stiff, standing up stiff in the wound, and adherent to the omentum. It was tied off about one-fourth an inch from the intestine; the mesentery was tied and removed. On account of the very great thickness of the walls of the appendix, it was impossible for me to invaginate it, so I covered it with a flap of omentum. The lumen of the stump I cauterized with the actual cautery. The wound was sewn up without drain. The young man made a perfect recovery, and has never had a return.

I had at that time another case, in which there had been a number of attacks. In the last attack which came to my attention, it went on to the formation of a tumor, which could be diagnosed by the rectum as well as over the iliac fossa, and there was a point in the rectum which seemed as though it was soft and fluctuating; there was a crater, such as you find in a softening abscess. It was thought best to operate in the ordinary way. This I did with the assistance of Dr. Elliot, who lifted the tumor from the rectum, and was enabled to puncture and evacuate the pus. He made a very good recovery in the ordinary way, as that class of cases do.

When I was about to show the first case to the Medical Society, I was going to find out what had become of this second case. On the very morning of the day when I made my report, this man appeared in the accident-room with another attack. I said to him, on seeing him in the ward, "How many attacks have you had in the last year?" He said, "I

have had so many attacks that I have not kept account of them." It was one of the milder attacks. When he recovered, I proposed to him, the removal of the appendix. It was done; and he made an uninterrupted recovery in the same way as the other.

Since these cases were reported I have operated a third time. The last case I showed to the gentlemen who were at the hospital this morning. The man, who is now twenty-six years of age, had been having attacks at long intervals since he was thirteen years of age. For four months previous to this operation he had been confined to bed by the lameness, and had lost flesh and was without appetite. He was transferred to the surgical wards, and I operated upon him. In connection with the case, I want to mention a fact which I think is well recognized by operators, and that is the very great difficulty which sometimes arises in finding the appendix. Dr. Homans has made the observation that the appendix may be found by following down the longitudinal bands upon the large intestine. That is the first rule, and the only rule I know of. Dr. Fitz, Dr. Warren, and Dr. Shattuck were present at the operation that I speak of, and I could not find, nor could any one else of those present find, anything which would lead to the appendix in this case, and I had the cecum in my hand. It was almost decided that a little knob on the cecum must be taken as an abnormal appendix, and we had not found the cause of the trouble. I said, "We have looked everywhere where it should be, let us look where it ought not to be." By lifting the cecum further up towards the crest of the ilium, lifting that up till it was turned up from its bed, there lay the appendix, nearly as large as my finger. It was so long that one of the gentlemen present made the observation that the kidney came down and touched the appendix. That was dug out and ligated in the ordinary way and treated as the other. A number have spoken about the difficulty in finding the appendix.

In connection with this, I want to go back to the case that Dr. Homans reported, where he removed the appendix in an acute attack, after a number of subacute attacks. I am especially interested in this case, because in the last attack before Dr. Homans operated I had him in my care. I decided that he should be operated upon, and the young man consented. In my endeavor to furnish my class with cases, I assigned this case to one of the students, and he unfortunately expressed to this young man the possible danger, although I had already told him the dangers; and the young man the next morning had decided that he would not have it done. When he came back with an attack so acute that he was operated upon, I felt that he might die because of the attack, and I felt that if that young man died probably his death was at my door, and I followed him with more interest than any other case that I had at the hospital during my service while he was under Dr. Homans's care.

Now I am to confine myself to the subject of recurrent appendicitis. This last winter I read a paper before the Medical Society, and at that time I was enabled to find fifteen cases, including my own. I knew, however, that there were a number of other cases that had not been reported, in the hands of the different surgeons here in Boston; and one of my class, in writing on the subject, had found twenty cases. We have not got any very large number from which to generalize with regard to which are the suitable cases, but it

seems to me that any man or woman or child who is invalidated for any considerable length of time, who is unable to follow the ordinary avocations of life from constantly recurring attacks of appendicitis, after being told what the dangers are, should be offered the relief of an operation; that those people who are obliged to travel; who are obliged to go away from the place where they can get good surgical aid, should be operated upon in the remission between the attacks; and it is especially to these two classes of cases that the operation should be limited.

With regard to the dangers, every one of the fifteen cases that I found recovered. Now I know by hearsay, but have not seen it in publication, that there are cases that have died from this operation. That must go without saying, that a laparotomy cannot end in complete recovery in every instance, no matter how carefully done or by whom. Against this operation it has been urged that ventral hernia sometimes follows, and that a man's last estate is worse than his first. It is well recognized that all surgeons open the abdomen at times as a mere means of diagnosis, and in cases where the disease is not threatening to life, and where there is not so good an opportunity to relieve as in these cases, so that it seems to me that the question of ventral hernia could not be considered; and not only that, but a man who thoroughly appreciates the best methods of closing the wounds will close his peritoneal surfaces first, then his muscular tissues second, and the skin last; and in that way he has made a wound which is as near proof against ventral hernia as human skill can make it, it seems to me.

Secondly, if a person must come for operation, how much better if he might come in the remission between the attacks, when you have not a purulent wound to deal with, but you can do everything with the greatest antiseptic precautions, and carry out every detail of asepsis, closing the wound throughout. You don't have to leave a drainage-tube in, which certainly, to my mind, could be nothing more than forming a diverticulum through which a hernia might find its way.

Now it seems to me that these are important points in connection with the operation in the remission between the attacks, and I feel sure that the surgical mind is growing toward the line of operating. If you are in doubt whether to operate or not I believe that the proper thing is to operate, and that it is a good deal better to give the patient the benefit of the doubt than to take it yourself.

(To be continued.)

## Recent Literature.

*Sexual Neurasthenia (Nervous Exhaustion): Its Hygiene, Causes, Symptoms and Treatment, with a Chapter on Diet for the Nervous.* By GEORGE M. BEARD, A.M., M.D. Posthumous manuscript, edited by A. D. ROCKWELL, A.M., M.D. Third edition, with formulas. 8vo, pp. xi, 282. New York: E. B. Treat. 1891.

In the present edition of this work Dr. Rockwell has added various suggestions in the way of the treatment of the conditions described by electricity, and has added various formulae. As the work is already familiar to the profession, an extended notice is unnecessary.

## EVOLUTION OF MEDICAL SCIENCE OUT OF THE MEDIEVAL VIEW.

UNDER the title of "New Chapters in the Warfare of Science," Dr. Andrew White, ex-president of Cornell University, has thrown together from various sources, an interesting and instructive sketch<sup>1</sup> of the struggles which medical progress has had to maintain against the theological spirit, tracing the evolution of medical science out of the mediæval view and its modern survivals. Everywhere for centuries he finds cropping out the feeling among ecclesiastical authorities that, with the abundance of supernatural means, there was something irreligious in seeking cure of disease by natural means. In Scripture, King Asa trusted to physicians rather than to the priests of Jahveh, and so died. St. Bernard declared that monks who took medicine were guilty of conduct unbecoming to religion. The School of Salerno was held in aversion by strict churchmen, since it prescribed rules for diet, thereby indicating a belief that diseases arose from natural causes and not from the malice of the devil. Pope Innocent III, early in the thirteenth century, forbade physicians, under pain of excommunication, to undertake medical treatment without calling in ecclesiastical advice.

From this feeling grew the classification of scientific students generally with sorcerers and magic-mongers, from whence the proverb, "Ubi sunt tres medici ibi sunt duo athei." As a result, the study of medicine was largely confined to the lowest order of practitioners, and subsequently to the Jews.

From the same feeling developed the doctrine of Signatures: that the Almighty must have set his sign upon the various means of curing disease which He has provided—a doctrine which in practice survives in the cosmetic use of bear's grease, originally considered a desirable application for baldness, as coming from an animal thickly covered with hair.

The enormous development of miracles, continuing century after century, which changed a natural and laudable veneration for the relics of martyrs into pure

<sup>1</sup> Popular Science Monthly, May and June, 1891.

fetichism, provided the church with a means of treating disease which she considered far better than scientific methods in medicine; and hence a cause of hostility. Why seek to build up scientific medicine, when relics, pilgrimages, sacred observances and the King's touch were curing hosts of sick people in all parts of Europe and England! The theological views of what the body *ought* to be, as exemplified by the missing rib and the hypothetical bone serving for the necessary nucleus of the human body for resurrection purposes, were hostile to and incompatible with the study of anatomy as prosecuted by Vesalius and drove him to exile and death.

The same spirit crops up later in Boston, in the opposition to Boylston's introduction of inoculation, notwithstanding the support he received from the Mathers and others, which averred that the small-pox "is a judgment of God on the sins of the people and to avert it, is to provoke him more"; that inoculation is an encroachment on the prerogatives of Jehovah, whose right it is to wound and smite. The same sentiment, one hundred and twenty-four years later, faced the Board of Health of Montreal during the small-pox epidemic of 1885.

In 1591, a lady of rank, charged with seeking aid for the relief of pain at the time of the birth of her two sons, was burned alive on the Castle Hill of Edinburgh.

In 1847 Sir James Simpson's use of chloroform as an anesthetic in obstetrical cases, was denounced from pulpit after pulpit, as impious and contrary to Holy Writ, the ordinary declaration being that its use was "to avoid one part of the primeval curse on woman." Finally, in desperation, Simpson brought to his aid the twenty-first verse of the second chapter of Genesis, as the record of the first surgical operation ever performed, in which the text proves that the Maker of the universe, before he took the rib from Adam's side for the creation of Eve, "caused a deep sleep to fall on Adam." To this the theological spirit replied that the "deep sleep of Adam took place before the introduction of pain into the world — in a state of innocence." Simpson finally won his battle with the aid of Thomas Chalmers.

Dr. White thinks that the progress in medical science within the past twenty-five years has been vast indeed, but that the world is hardly beyond the beginning of medical discoveries. In three fields especially, according to his view, discoveries have been made which have done much to disperse the atmosphere of miracle: (1) in the greater knowledge regarding the relation between imagination and medicine; (2) in hypnotism; (3) in bacteriology. The theological view of disease has greatly faded, and the theological hold upon medical education been almost entirely relaxed.

Dr. White notes two main facts in summing up the long struggle between science and theology: First, that in proportion as the world approached the "Ages of Faith," it receded from ascertained truth; and in proportion as the world has receded from the "Ages of

Faith," it has approached ascertained truth. Secondly, that in proportion as the grasp of theology upon education tightened, medicine declined; and in proportion as that grasp has relaxed, medicine has been developed. In this development, medical discoveries, sweeping away the belief in miracles, have cleared higher paths, not only for science, but also for religion.

#### ELIMINATION AND ITS USES IN PREVENTING AND CURING DISEASE.

THE above was the title of the Cavendish Lecture, delivered June 12th, by Dr. T. Lauder Brunton. Particular emphasis was placed on the importance of free elimination by the bowels. Not only the brain, but the heart, lungs, liver, stomach and kidneys have their functions impaired when the bowels cease to do their duty. Napoleon's disaster at the battle of Leipzig is popularly set down to his having eaten a bun in a hurry, and so brought on dyspepsia; but it would be a very curious page of history if we could learn how many wars, how much bloodshed, and how much cruelty have had their origin in imperfect action of the bowels. Washington Irving, in his "Lives of the Caliphs," tells of a certain emir named Al Hejagi, who suffered for many years from dyspepsia and abdominal pains, and this wretched man distinguished himself, perhaps above all other rulers who ever lived, in the enormous number of people whom he sentenced to imprisonment and death. He is said to have caused the death of no less than 120,000 persons, besides those who fell in battle, and to have left 50,000 in prison when he died himself. How much of all this misery might have been averted by the judicious use of mild aperients, it is as impossible for any one now to tell, as it is to estimate the debt of gratitude which Europe owes to the physician of Louis XIV for the care he took of the bowels of that august monarch.

In mitral disease and in dropsy, either cardiac or renal, the benefit derived from the free use of the compound jalap powder is very great; and in his work on "Purgative Medicines," Dr. Hamilton describes most forcibly the advantages he obtained from purgatives employed in such a way as merely to clear the bowels, not to produce violent purging, in typhus fever, malaria, scarlet fever, hysteria, chorea and tetanus.

Most persons can regulate their bowels by exercise and diet, but these sometimes fail, and we must have recourse to so-called aperients. The dinner-pill supplies a very useful stimulus, and Dr. Brunton knows a man who has taken one every day of his life for forty years, apparently with great benefit to himself. But there are some people who do not seem to thrive on dinner-pills, and they either do not get any action at all, or they get too much. In such cases, instead of giving the intestines one great push once a day by the dinner-pill, one may give them a series of gentle jogs by adding to each meal a minute quantity of a purgative; and Dr. Brunton has found that one-tenth of a grain of aloin given with each meal sometimes succeeds

when other means fail, and even these minute doses sometimes seem to be too much.

But many persons, besides the dinner-pill, require a weekly clear-out; and if this be not given to them by means of a cholagogue purgative, they have a regular sweep-out once a month by getting a violent migraine with bilious vomiting; and generally they are obliged to fast for at least one day during the continuance of the headache. The effect of a cholagogue purgative such as a mild mercurial, followed by some saline, is sometimes very remarkable. Dr. Brunton has seen a quarter of a grain of calomel, with a Seidlitz powder next morning, surprisingly change the temper of a sulky boy or girl; and he has more than once taken the "naughtiness" out of a peevish child by a dose of Gregory powder, which, being nasty to the taste, has both a moral effect and a physical action.

Not infrequently adults suffer from nervous irritability, depression, weakness, and inability to do anything; and this is often put down to neurasthenia and hypochondriasis. They are treated with nerve tonics and sedatives, change of scene, baths, etc., to little purpose; nervous and depressed they still remain. In some of these cases, we may notice a large amount of mucus in the motions, and sometimes there appear to be actual casts of the intestines, long membranous-looking shreds, apparently tubular in their character. This condition has been described by Dr. James Simpson, under the name of "membranous enteritis"; and it is not only usually said to be associated with hypochondriasis, but often it is looked upon as a consequence rather than the cause of the nervous condition which is its usual concomitant. But it is no use here to treat the nerves. If you wish for any good result, you must treat the bowels. In some, probably many cases, conditions depends upon partial constriction of the intestine near the junction of the sigmoid flexure with the rectum. The motions, lodging here, cause an inflammatory condition of the mucous membrane and profuse secretion of mucus, which either simply coats the fecal matters, or forms a kind of false membrane. In adults, prolapse of the sigmoid flexure into the rectum may give rise to great nervous disturbance lasting for years, unless its existence be suspected and the proper treatment adopted. One useful remedy is the injection of two to four ounces of cold water immediately after a motion. This is to be retained, and has the tonic effect of a cold bath on the intestine, increasing the contractile power and lessening the tendency to prolapse. In all cases of this kind the regular use of suitable laxatives should be enjoined.

Dr. Brunton, in the same lecture, urges the importance of maintaining a healthy state of the renal function, and speaks of the benefit in gouty and rheumatic cases, and in bilious colic, of making patients drink a big tumbler of water, and especially hot water, every morning, with or without some Karlsbad salts added to it, and, if necessary, repeating the hot water once or twice in the day.

## MEDICAL NOTES.

**A COMMENT ON THE ACCURACY OF VITAL STATISTICS.**—The New York City Board of Health notified physicians that there was a neglect in reporting births. The result of the notice was an increase in births in two succeeding weeks of from 697 to 1,288.

**RESIGNATION OF DR. RAUCH.**—Dr. John H. Rauch's resignation as Secretary of the State Board of Health of Illinois was tendered and accepted at the meeting of the board held in Chicago, on June 30th. Dr. Rauch has been a member of the board since its organization, in 1877, during which time his work has been of national importance and utility.

**INEBRIETY AND MEDICAL PRACTICE.**—The Secretary of the State Board of Health of Iowa announces that he is convinced that habitual drunkenness constitutes "palpable evidence of incompetency," as the law reads, and that therefore the physician bound by inebriety should be deprived of his certificate entitling him to practice in that State.

**THE PULSE-RATE AT DIFFERENT AGES.**—Langlois has investigated this subject thoroughly, and gives the following results for the normal pulse: Between the ages of fourteen and forty-five the normal rate is very nearly 70 beats per minute. Below the age of fourteen the normal rate may be found by the formula  $P = 140 - 5A$ ; the pulse-rate being represented by P, and the age by A. After the age of forty-five it is found by the formula  $P = \frac{1}{2}(95 + A)$ .

**NEW MEDICAL PERIODICALS.**—A bi-monthly journal, to be known as the *Vis Mediceatrix* appeared for the first time in June. It is the journal of the Iowa State Medical Society, and will also have departments devoted to the treatment of animals and plants. It is published in Des Moines, under the editorial charge of Woods Hutchinson, M.D. The *Ophthalmic Record*, containing, besides articles on diseases of the eye, a department of laryngology, rhinology and otology appears this month in Nashville, Tenn. It is to be published monthly. A monthly journal entitled *Blätter für klinische Hydrotherapie* appeared for the first time in May. It is published in Vienna under the charge of Prof. Wilhelm Winternitz, and will be devoted to balneology and kindred subjects.

## BOSTON AND NEW ENGLAND.

**MORTALITY OF BOSTON.**—The summary of vital statistics of the city of Boston for the six months ending June 30, 1891, as compared with the same period for 1890, shows the number of deaths in 1891 to be 4,982, against 5,155 in 1890. The number of cases of diphtheria have been 411, with 104 deaths in 1891, 976 cases and 258 deaths in 1890. Scarlet fever and typhoid fever have been nearly the same. There have been reported 2,423 cases of measles with 20 deaths in 1891, against 426 cases with 9 deaths in 1890. The small amount of diphtheria during the past year is

unprecedented. Consumption, pneumonia and heart disease also show a decrease in deaths. The statement of mortality for the month of June shows the number of deaths to be 736, with the death-rate per 1,000 at 19.23. Of those who died, 360 were males and 376 females; 216 were married and 394 single; 88 were widows and 32 widowers; 715 were white and 21 were colored. The number of children who died under one year of age, was 152. There were seven deaths due to alcoholism, 23 from cholera infantum, 16 by diphtheria, three from influenza, two from measles, four from typhoid fever, 27 from cancer, and 25 from tuberculosis.

**COTTAGE HOSPITAL IN DEDHAM.**—A charter has been granted to the Dedham Cottage Hospital, "for establishing and maintaining a cottage hospital for all the purposes for which such institutions are created," in the town of Dedham.

**TYPHOID FEVER IN RHODE ISLAND.**—An epidemic of typhoid fever, of considerable extent, is reported from Valley Falls, R. I. The first cases occurred in the middle of May.

#### NEW YORK.

**MORTALITY IN NEW YORK CITY.**—The number of deaths reported in the city during the week ending July 4th was 922. This is an increase of 119 over the mortality of the preceding week, but is nearly 200 below the average for the corresponding week during the past five years. It represents an annual death-rate of 28.61 per 1,000 of the estimated population, as against 31.50 for the five-year computation. This favorable result is no doubt due in great measure to the cool weather that prevailed during the week. As it was, there were 240 deaths from diarrhoeal diseases, and of 544 deaths of children under five years of age, 400 were in infants under one year. There was a notable decrease in the deaths from respiratory diseases, and also from contagious affections. Some of the figures are as follows: Pneumonia, 56; bronchitis, 22; phthisis, 72; measles, 16; scarlet fever, 21; diphtheria, 21. The mortality from typhoid fever was remarkably small, there being only two deaths from this cause.

**CITY BOARD OF HEALTH.**—The two months' service of the summer corps of fifty physicians of the Board of Health commenced on July 6th. They are required to spend eight hours a day in house-to-house visitation among the tenement population, which is divided into fifty districts, and to report twice a week to Dr. Moreau Morris, who is the director of this special work.

**EXECUTION BY ELECTRICITY.**—Although all the witnesses present at the execution of the four murderers at Sing Sing prison on the 7th of July were pledged to secrecy concerning the event, there can be no question that in every instance death was perfectly painless and instantaneous, and that the new electric method proved a complete success. Under the direc-

tion of Dr. Carlos F. McDonald, President of the State Commission in Lunacy, who had been asked by Governor Hill to supervise the executions, the electrodes were placed at the forehead and the calf of the leg, instead of at the top of the head and the lower extremity of the spine, as in the case of Kemmler.

**UNIVERSITY OF THE CITY OF NEW YORK.**—At the opening session of the twenty-ninth convocation of the regents of the University of the State of New York, held in Albany, July 8th, 9th and 10th, the president, Hon. George William Curtis, conferred the honorary degree of M.D. upon Herbert M. Dayfoot of Rochester, and John T. Talcott of Oswego. The principal subject discussed was the question, "Shall gymnastics be ranked as a study?" And among those who spoke in favor of athletics among students were President Hitchcock of Amherst College, President Webster of Union College, Dr. Luther Gulick of Springfield, Mass., and Dr. W. T. Harris.

#### Miscellany.

##### A METHOD OF CUTTING GLASS BOTTLES, TUBES, ETC.

MR. WM. THOMSON<sup>1</sup> recently read some papers before the Society of Chemical Industry, one of which treated of this subject.

The method consists in having some strips of thick blotting paper at hand, from a quarter to half an inch in width, and of different lengths. Two pieces of such paper are wetted and wrapped around the bottle, tube, or other vessel to be cut, once or oftener (once is sufficient). These pieces of paper, cut true, are wrapped around the vessel like two bands. They must not be placed too close together—say from a quarter to three-eighths of an inch apart for larger vessels, and rather less than a quarter of an inch apart for tubes of an inch in diameter.

When this is arranged, a fine flame about two or three inches long is allowed to play on the glass between the two pieces of wet paper, the vessel being slowly revolved and the point of the flame kept between the two papers. Within a minute, usually, the vessel separates with a clean cut along the line against which the flame played. The blotting paper can then be removed and put aside for use on other occasions.

##### THE PART PLAYED BY MICROBES IN SUPPURATION.

In the course of a discussion at the recent French Congress of Surgery<sup>2</sup> on the different forms of suppuration, examined from bacteriological and clinical points of view, the following conclusions were laid down by M. Verneuil:<sup>3</sup> Microbes are necessary for pyogenesis, pus is the function of microbes; there are many known pyogenic microbes, but the number of these has not yet been made out; some are constantly pyogenic and nothing more, others seldom produce pus and are pre-eminently infective; the centres of

<sup>1</sup> American Druggist, June 1st.

<sup>2</sup> British Medical Journal, June 25th.

<sup>3</sup> Revue de Chirurgie, May.

suppuration are in some instances, mono-microbic, in others poly-microbic; in poly-microbic purulent centres there are three kinds of association — one of different agents that are all invariably pyogenic, another of invariable with occasional agents of suppuration, and a third of pyogenic with non-pyogenic agents; a purulent centre originally mono-microbic may become poly-microbic; a substitution of one kind of microbe for another kind may take place in a centre of suppuration; the collection of pus may become amicrobic, the pyogenic agent may disappear and the pus become sterile; microbes which engender pus pervade the whole region of suppuration; pyogenic microbes do not always excite suppuration nor at the time of invasion; the vitality of pyogenic microbes varies in the different forms — some disappear very quickly, others retain their vitality for almost indefinite periods; suppuration may in every instance be regarded as due to the presence of bacteria; the specificity of microbic agents being assumed, it becomes necessary to make out the specific action of each form of microbe. From these etiological conclusions one may readily deduce certain therapeutical indications: In cases of open suppuration, as, for instance, unhealed wounds and carbuncle, the treatment should consist in prolonged antiseptic baths, and in the application of antiseptic powders; if the suppuration be intralermic, as in lymphangitis and erysipelas, the application of antiseptic powders will suffice; if the suppuration be deep seated, one must penetrate into the collection in order to evacuate the pus and to sterilize it. Free incisions are useless; all that is necessary is to let out the pus through a small incision, and to replace it by a microbe-killing agent.

#### ST. VITUS DANCE.

An outbreak of an epidemic of chorea in a school in Wildbad, reported<sup>1</sup> some months ago, recalls the dancing manias of the middle ages, which were at that time called the dances of St. John and St. Vitus.<sup>2</sup> Whether or not these outbreaks were of the same character on a large scale as the occasional outbreaks of chorea at the present day, or as the wild gestures and cries sometimes observed at religious revivals, it seems certain that with our present civilization wide spread epidemics are impossible.

In the year 1371 the dance of St. John assumed that severe and epidemic character which has made it memorable. In this year bands of men and women from different parts of Germany appeared at Aix-la-Chapelle. They paraded the streets, and besieged the churches. They joined hands, and, regardless of observers, indulged in the wildest gestures and the maddest dancing until they fell down in a state of exhaustion. They rolled upon the ground, foamed at the mouth and gnashed their teeth. They groaned as if in the agonies of death, and relief could only be obtained by tying a band tightly around the waist of the sufferer. The object of this was to relieve the tympanites, which was a prominent symptom, but other and more forcible methods, such as thumping and tramping upon the parts affected, were not uncommonly resorted to for the relief of this condition. While the dancing continued its votaries were in a state of ecstasy. They were oblivious of their sur-

roundings, they saw signs and visions; to them the heavens were opened, and the Saviour enthroned with the Virgin become visible. From Aix-la-Chapelle the epidemic quickly spread over the Netherlands, and all the arts and rites of the Church were invoked against it.

It was forty years later that a similar epidemic broke out at Strasburg, and to this the name of the dance of St. Vitus was first applied. The name had reference to the fact that this saint was supposed to have special power in overcoming the disease, and his shrines in various places became the resort of the afflicted. The association of this saint with the affection was no doubt due to a legend, in all probability invented for the occasion. St. Vitus was a Sicilian who had suffered martyrdom in the fourth century, and, according to the legend which now became current, just as he bent his neck to the sword he prayed that he might protect from the dancing mania all who kept his commemoration day and fasted upon its eve. In answer to this a voice was heard to say, "Vitus, thy prayer is answered," and henceforth St. Vitus became the refuge and protector of all who suffered from this dancing mania.

#### THERAPEUTIC NOTES.

**NEW REMEDIES FOR MALARIA.** — Pambotano, a small tree growing in Mexico, was extolled by Valude, in 1889, as a remedy for malaria. Dr. A. E. Roussel, in a recent paper read before the Philadelphia County Medical Society, described his use of a decoction and an alcoholic elixir of the plant. His results were decidedly encouraging, although not as satisfactory as had been reported from abroad.

Dr. Capus states<sup>1</sup> that in a hospital in Turkistan excellent results have been obtained in the treatment of all forms of malaria by sprays of the essence of cinnamon. Even cases which have resisted the action of quinine and arsenic improved in a few days under this treatment. The spraying is performed several times daily in the hospital wards, and is stated to be much more efficacious than a similar procedure with the essence of eucalyptus.

**THE STINGS OF INSECTS.** — The *Deutsche medicinische Wochenschrift* recommends rubbing the bites immediately with sea-water, or a solution of sea-salt.

Dr. Wm. A. Terry<sup>2</sup> has obtained good results by the application of fresh urine.

**STRYCHNINE IN SNAKE-BITE.** — Dr. Mueller, of Victoria, uses the following injection:

R Strychnine nitrat	1 part.
Aqua destil.	240 parts. M.
A little glycerin may be added.	

Twenty minims of this solution are injected hypodermically, and the frequency of repetition depends upon the symptoms being more or less threatening, say from ten to twenty minutes. When all symptoms have disappeared, the first independent action of the strychnine is shown by slight muscular spasms, and then the injections must be discontinued, unless after a time the snake poison reasserts itself. The quantity of strychnine required in some cases has amounted to a grain or more within a few hours. Both poisons are thoroughly antagonistic, and no hesitation need be felt

<sup>1</sup> *Lancet*, January 30th.

<sup>2</sup> *Ibid.*, March 1st.

<sup>1</sup> *La Pratique Medicale*, April 7th.

<sup>2</sup> *Diabetic Gazette*, June.

in pushing the use of the drug to quantities that would be fatal in the absence of snake poison.

**MOUTH WASH.**—Dujardin-Beaumetz is said to recommend the following\* to keep the teeth in good condition :

R	Acidi carbolici . . . . .	gr. xv.
	Acidi borici . . . . .	3 vi.
	Thymol . . . . .	gr. viii.
	Ol. menth. pip. . . . .	gtts. xx.
	Tinct. anisi . . . . .	ss liiss.
	Aque . . . . .	O ij. M.

This should be mixed with an equal part of water, and used two or three times a day.

**VON GIETH'S DRESSING FOR THE CHEST.**—Parker<sup>4</sup> gives the details of Von Gieth's dressing for pneumonia and pleurisy. *Pure* olive oil (no other substance will be just as good) is poured in sufficient quantity into a previously warmed bowl, and a strip of soft cotton cloth, large enough to encircle the chest, is placed in the bowl and completely saturated with the oil. This is then applied to the patient's chest, and outside of it a second strip of dry cloth is placed, and, if necessary, a third, which completes the dressing. This application is said to be most acceptable to patients, and more successful in results than poultices, stupes or other local dressings more commonly in vogue.

**MICROSCOPIC PREPARATIONS OF LUNG TISSUE.**—According to Dr. John Aulsebrook a section of lung tissue may be prepared in the following way : It is thoroughly washed with water, then with alcohol and de-alcoholized. A mixture of oil of cloves and oil of cedar, mixed in such proportions that a glass rod introduced into the mixture shows no angular refraction, is introduced into the lung tissue, and the whole covered with paraffine wax and a little resin, and then dipped into ice water. It can then be readily cut with a knife.

## Correspondence.

### EVIDENCE AS TO THE INJURIOUSNESS OF ARSENIC AS A DOMESTIC POISON.

PARIS, June 24, 1891.

MR. EDITOR:—I ask your permission to restate, in a somewhat different form, the substance of what I desired to emphasize particularly in the discussion of Dr. J. J. Putnam's excellent paper upon "The Character of the Evidence as to the Injuriousness of Arsenic as a Domestic Poison."<sup>1</sup>

Taking a large number of cases, it may be assumed that the gravity of the poisoning will be in proportion to the quantity of the poison absorbed, and statistics regarding classes of persons exposed in different degrees to arsenical poisoning will have more weight than reports of individual cases, and particularly when the legal responsibility of manufacturers is to be determined.

(1) Some mysterious cases have been reported in which poisoning has been attributed to an arsenical wall-paper covered by another paper free from arsenic. Here it is impossible to suppose that dust rubbed from the paper is the source of poisoning, and the formation of arsenuretted hydrogen has been suggested as the cause. The test for arsenic in arsenuretted hydrogen gas is of extreme delicacy; but thus far all attempts to obtain evidence of a formation of arsenuretted hydrogen from wall-paper have

failed, and we must conclude that only infinitesimal quantities, if any, are given off by wall-paper. On the other hand, a class of persons is frequently exposed to quantities of arsenuretted hydrogen large enough to be readily detected. There are students engaged in tests for arsenic, and still more commonly, those who experiment with hydrogen made from impure metals, which usually contain arsenic; workmen who fill balloons, lime-light apparatus, etc.,—these classes of persons are exposed to poisoning from arsenuretted hydrogen, if "imponderable" quantities of the gas are poisonous.

(2) Poisoning from arsenic in the form of arsenious acid. Physicians are in the habit of prescribing Fowler's Solution in minimum doses of three to six hundredths grain of arsenious acid per diem. Taking this quantity as a standard for comparison, it can be shown that the quantity of arsenious acid in the dust falling from an arsenical wall-paper, which could be inhaled by the inhabitant of a room, is one hundred or one thousand times less than the amount of arsenic, which is usually considered not poisonous in prescriptions of Fowler's Solution, because the inhabitant of a room avoids as far as possible breathing the dust. On the other hand, a house-maid is forced to do so, and more frequent cases of poisoning should be looked for among this class of persons.

(3) Another class of persons who are particularly exposed to breathing arsenical dust have not thus far been recognized by physicians as carrying on a dangerous occupation. The dust of chimney-flues has been lately found to contain large quantities of arsenious acid,—many thousand times more than the dust of a room with arsenical wall-paper. Even with the modern appliances, considerable quantities of this dust are inhaled by chimney-sweeps, and the frequency of poisoning should be investigated in this case. From the same source, the exposure to arsenical poisoning is much greater in certain towns where a bad quality of coal is burnt abundantly in open fireplaces, as is the custom in England or in Pennsylvania.

In conclusion, I would point out that medical diagnosis has thus far not led the way to the discovery of new sources of arsenical poisoning. Various forms of illness are attributed to this cause only since chemists have made known the presence of arsenic in certain fabrics. The extreme differences of susceptibility of individuals and the variety of the pathological symptoms make the medical evidence an uncertain guide. It is for this reason that I wish to insist upon the importance of collecting a larger body of statistics; and for one item, of pursuing further the inquiry into the relation between the prevalence of poisoning and the quantities of arsenic to which classes of persons are exposed. This mode of inquiry seems to be of special value where legislative enactments are in question.

Yours truly, J. M. CRAFTS.

### METEOROLOGICAL RECORD,

For the week ending July 4, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Barometer	Thermometer	Relative humidity.	Direction of wind.	Velocity of wind.	Wet't. *	Rainfall in inches.

Peabody	10,158	1	1	—	—	—	—	—			

Deaths reported 3,566; under five years of age 2,026; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,080; consumption 305; acute lung diseases 24; diarrhoeal diseases 800; diphtheria and croup 18; typhoid fever 57; scarlet fever 48; measles 33; whooping-cough 26; cerebro-spinal meningitis 18; malarial fever 6; erysipelas 3.

From scarlet fever New York 24, Brooklyn 7, Chicago and Philadelphia 5 each, Baltimore 3, Cincinnati, Milwaukee, Lowell and Cambridge 1 each. From measles New York 16, Brooklyn 7, Chicago 6, Pittsburgh 3, Charleston 1. From whooping-cough New York and Chicago 5 each, Philadelphia, Baltimore, Pittsburgh and Washington 3 each, Brooklyn 2, Milwaukee and Nashville 1 each. From cerebro-spinal meningitis Chicago 7, New York and Washington 3 each, Milwaukee 2, Philadelphia, Brooklyn and Taunton 1 each. From malarial fever Brooklyn and Baltimore 2 each, Nashville and Charleston 1 each. From erysipelas New York, Baltimore and Milwaukee 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,405,408, for the week ending June 27th, the death-rate was 20.1. Deaths reported 3,680; acute diseases of the respiratory organs (London) 139, whooping-cough 117, measles 72, diarrhoea 64, diphtheria 36, fever 26, scarlet fever 24.

The death-rates ranged from 16.0 in Cardiff to 28.3 in Wolverhampton, Birmingham 23.5, Bradford 17.8, Hull 20.0, Leeds 18.8, York 27.8, Liverpool 25.8, London 19.0, Manchester 23.9, Nottingham 17.9, Sheffield 18.1, Sunderland 19.5.

In Edinburgh 18.9, Glasgow 25.6, Dublin 17.9.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 1, 1891, TO JULY 10, 1891.

A. Assistant Surgeon JAMES W. BELL is retired from active service, by reason of disability incident to the service.

A. Assistant Surgeon WILLIAM S. OWEN, Jr., detailed to attend the encampment of the Illinois National Guard, near Springfield, Ill., from July 18 to 25, and August 11 to 18, 1891.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 11, 1891.

ROBERT BOYD, assistant surgeon, ordered to the U. S. R. S. "Dale," Washington, D. C.

## SOCIETY NOTICES.

VERMONT STATE MEDICAL SOCIETY.—The annual meeting will be held in Burlington, October 15th and 16th. The President's Address will be delivered by Dr. J. N. Jenne, of St. Albans. The annual banquet will take place on Thursday evening, October 15th, after the President's Address, with Prof. J. H. Jackson, of Barre, as Anniversary Chairman. There will be the usual exhibit of drugs, medicines, surgical instruments and appliances, etc. The regular program will be issued October 1st.

D. C. HAWLEY, M.D., Burlington, Secretary.

AMERICAN PUBLIC HEALTH ASSOCIATION.—The nineteenth annual meeting will be held at Kansas City, October 20-23, 1891. The executive committee have selected the following topics for consideration at said meeting: (1) Sanitary construction in house architecture; (2) heating; (3) lighting; (4) drainage; (5) ventilation; (6) Railroad sanitation; (7) Meat supplies; (8) Milk supplies of cities; (9) Arsenical papers and fabrics; (10) Isolation hospitals for infectious diseases in cities; (11) Papers upon any of the subjects upon which special committees have been appointed; (12) Papers on miscellaneous sanitary and hygienic subjects.

All communications relating to local matters should be addressed to E. R. Lewis, M.D., Chairman Local Committee of Arrangements, Kansas City, Mo.

Another circular will be issued before the meeting, giving transportation rates, hotel rates, etc.

Blank applications for membership can be obtained by addressing the Secretary or Chairman of the Local Committee of Arrangements.

IRVING A. WATSON, Secretary.

## APPOINTMENT.

William W. Gannett, M.D., has been appointed Visiting Physician at the Massachusetts General Hospital.

## DEATHS.

WILLIAM W. JONES, M.D., of New York, died, July 11th, aged seventy-eight. He graduated from the College of Physicians and Surgeons in 1842. He was Visiting Physician to the Northern Dispensary, Attending Physician to St. Luke's Hospital, and Consulting Physician to the Nursery and Children's Hospital, and the New York Asylum for Lying-in Women.

ARTHUR E. Z. VINCIGLLETTE, M.D., M.M.S.S., of Lowell, died in Quebec, July 3d, aged thirty-seven. He was born in the Province of Quebec, graduated from Laval University, and had practised in Lowell from 1883 until last year, when he went to Quebec, on account of his health.

DR. FRIEDRICH W. SEANZONI VON LICHTENFELS, Privy Counsellor of the Kingdom of Bavaria, and Emeritus Professor in the University of Wurzburg, died on June 12th, aged sixty-nine, after an illness which had lasted many years. He was a very active worker and writer. His great treatise on Midwifery first appeared forty years ago, and since that date he has written a text-book on Gynecology, which was translated into English (second-hand from the French) by Dr. Augustus K. Gardner, of New York, in 1861. Since that date he has written numerous monographs and contributions to medical journals and text-books.

## BOOKS AND PAMPHLETS RECEIVED.

The Surgery of Cleft Palate. By M. B. Ricketts, M.D., Cincinnati, O. 1891.

The Social and Medical Aspects of Insanity. By John Punt, M.D., Kansas City, Mo.

Lectures on Tumors. By John B. Hamilton, M.D., LL.D. Detroit: George S. Davis, 1891.

Hygienic Conditions of Passenger Cars. By Granville P. Com, M.D., Concord, N. H. Reprint, 1891.

The Indications for Early Laparotomy in Appendicitis. By William W. Keen, M.D., Philadelphia. Reprint, 1891.

Cancer of the Cervix Uteri in the Negroes; with Psycho-somatics. By Howard A. Kelly, M.D., Professor of Gynecology in the Johns Hopkins University. Reprint, 1890.

The Steps of the Cesarean Section: The Do's and the Don't's. By Howard A. Kelly, M.D., Professor in Gynecology to the Johns Hopkins University. New York: William Wood & Co. 1891.

## Lecture.

### NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

(Continued from No. 3, page 52.)

*Pathological Fatigue.*—In contrast with these normal processes may be placed the picture of the unbalanced conditions of waste and repair,—of expenditure and storage of energy,—the conditions of pathological fatigue, or neurasthenia. In a recent paper, valuable for its concise analysis of the subject, Dana<sup>12</sup> has given a comprehensive definition. He says, "Neurasthenia is a morbid condition of the nervous system whose underlying characteristics are excessive irritability and weakness"; it is "a condition in which the nutrition of the nerve-cells is primarily at fault." Can these phenomena be accounted for in default of anatomical and pathological findings?

It has been shown how inseparably normal fatigue from the discharge of tissue energy is accompanied by toxic products that increase the fatigue. Now every action of the mechanism is considered as aroused by some definite cause or stimulus. Stimulation too soon repeated, without giving time for rest and repair, finds nerve-cells in fatigued areas, having less power to act because of inanition from deficient rest and nourishment; they are also hindered in action by the incomplete removal of the toxic products of previous action,—in other words, there is inanition and auto-intoxication. Then further assimilation is hindered,—first, by the lessened nutritive quality of the blood from non-eliminated toxic materials,—and second, by the probable toxic weakening of the cells' power to assimilate the nutrition that is furnished them. The development of a manifestly morbid condition may be very slow and insidious, or more rapid according as the balance of the processes of constructive and regressive metabolism is more or less on the side of weakness, exhaustion and impoverishment. In explaining the effect of this gradually failing elimination of the products of metamorphosis, acting as an irritating and exciting intoxication, Kowalewsky<sup>13</sup> says, "there will then be a condition of partial inanition of the exhausted portion of the central nervous system, while, in the same part, partial auto-intoxication is going on, and while the remainder of the organism is in its normal condition. The result of a partial inanition will be an increased excitability on the one side, and, on the other, a quick exhaustion of the nervous system; these are the constant characteristics of neurasthenia. Thus a locally limited over-strain of a certain part of the nervous system may lead to exhaustion and neurasthenia."

It has been easy to understand how the "nervous weakness" so essentially characteristic of neurasthenia, should be a logical result of "exhaustion" by over-use; here is not only further explanation of this, but the "excessive irritability" is accounted for; tissues, weak from partial inanition, and, under constant stimulation from toxic irritation, almost excited into action, are over-sensitive upon the addition of ordinary stimuli.

It is a kind of "hair trigger" sensitiveness that amounts to hyperæsthesia.

The localized neurasthenic conditions being acquired in this way in an organism previously healthy, it is easy to see how "entire loss of strength in the whole nervous system" may come about, through its prolonged exercise without due intervals of rest. In the excess of nervous activity and of the metabolic processes, there appears to arise from the decomposition or "combustion" of tissues, a condition of general inanition from inability of nerve-cells to take up the nutriment and oxygen presented to them in the circulation. Kowalewsky describes this as a demand for oxygen in the whole organism, or oxygen-hunger. This tends to increase, by deprivation, the partial and local inanition; and obviously the blood may be charged with an excess of the products of regressive metamorphosis, through inefficiency of the eliminative processes,—often because of weakened innervation. Then, he says, there is general auto-intoxication which adds its influence to the limited and local neurasthenic condition that may have been previously established. From this reasoning we derive four principal factors that, as pathological conditions, operate in presenting the phenomena of neurasthenia, and make up its clinical picture:—

1. — Partial (local) inanition.
2. — Partial (local) auto-intoxication.
3. — General inanition.
4. — General auto-intoxication.

This leads to the conclusion that, in very many cases certainly, neurasthenia has its foundation amply accounted for. The condition of inanition and auto-intoxication, whether partial or general, may vary according to the presence of one or more of the factors and their different values in the particular case. The auto-intoxication will affect one mechanism, or organ, differently from another, according to the dissimilarity of structure and function; from different organs, or tissues, will come different kinds of toxic products, and their effect will vary also according to their amount. In anæmia, the general impoverishment of the blood, from its own diseases, will, of course, contribute to, and may initiate, both local and general neurasthenic conditions. Even when the blood-supply is ample there may be locally limited over-strain and nervous exhaustion, probably due in part to the inability to assimilate nutrition. The conclusion of this matter is that, in morbid conditions, nervous weakness from inanition, due to expended energy and lack of nutrition of the nervous system, has always joined to it the varied effects of auto-intoxication as a dual cause of neurasthenia.

*The Etiology of Neurasthenia.*—*Primary, Secondary, and Hereditary.*—The genesis of acquired neurasthenia in a healthy organism can thus probably be largely accounted for as a primary neurosis due to the immediate effects of over strain, or a primary and toxic disorder of nutritional functions. The principle may be equally well applied to the secondary neurasthenias,—those consequent upon other diseases, each with its peculiar exhausting and toxic influences, as the essential feature of a general pathological diathesis. It is, as yet, impossible to say what the chemical action in cell-protoplasm may be that causes the increased excitability and quicker exhaustion of nerve tissue, when they are consequent upon the chronic auto-intoxication of rheumatic and gouty diathesis; but the transmission

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.

<sup>12</sup> Art. Neurasthenia. The Post-Graduate, January, 1891.

<sup>13</sup> Centralblatt f. Nerven heilkunde, October, 1890.

of these diatheses by heredity we cannot doubt, nor that children inherit neuropathic and neurasthenic predispositions from rheumatic and gouty parents. The same is true of all the "constitutional" diseases. The transmission of the effects of nervous diseases, alcoholism, syphilis, etc., may sometimes be shown in structural changes and defects of the central nervous system,—sometimes, according to Arndt,<sup>15</sup> in permanent embryonic conditions from arrested development, but slightly demonstrable, and constituting the structural basis of hereditary neurasthenia. While this term may still be fittingly applied to those cases where there is only a predisposition to functional disturbances and disease of the nervous system, the close relationship of all these conditions to organic changes is apparent.

James J. Putnam,<sup>16</sup> in his study of the etiology of sclerosis of the spinal cord, notes the predisposition by neuropathic inheritance to degenerative change; the suggestion, by some pathological findings, of a strain of constitutional or developmental weakness; the general enfeeblement of the whole body through debilitating influences, as probably initial to a primary degeneration becoming relatively chronic; the increasing importance assumed by toxic influences like syphilis, lead, arsenic, etc., and their conjunction with conditions of simple impairment of nutrition as contributive; the influence of over-exertion with stimulation and sensory irritation inducing ganglionic exhaustion to a pathological degree, and the possible relation of acute to chronic local anæmia.

According to Klebs,<sup>17</sup> also, the most essential characteristic of all degeneration is the deposit in the tissue of substance derived from nutritive changes in the part. There are disturbances of assimilation caused either by the deposition of non-assimilable material or by a diminution of the power of assimilation of the tissue; and the material may originate in the part or be brought to it from without. As an example of this, fatty degeneration is one of the most frequent and important pathological conditions which occurs in conjunction with the protoplasmic structures and the deterioration of their functions. General fatty degenerations always arise from influences which are either of an infectious or toxic nature.

As to the processes of pure, real atrophy, Klebs says, we have to deal with two fundamentally different sorts of disturbances of nutrition, according as the necessary food is withheld from the parts, or the power to assimilate it is lessened. In the central nervous system, the frequency and significance of circulatory disturbance depend on the easy disturbance of the nervous elements in consequence of the withdrawal of nutrition. The mental functions may be greatly disturbed by even simple anæmias if continued a certain length of time. Probably material changes in the composition of the blood may aid in affording the local anæmia the time necessary for bringing about the process of atrophy. In favor of this is the connection of many acute mental disturbances with infectious diseases, and their occurrence after typhus, puerperal fever, and acute articular rheumatism.

*Pathology of Neurasthenia.*—These pathological considerations indicate the effects that may follow from such initial causes as cerebral fatigue, toxic influences,

lessened power of assimilation, local anæmias, etc., in the easily disturbed nervous elements. As the greater includes the less, we must regard the initial functional weakness and irritability of acquired neurasthenia, proceeding from the same causes, as their milder manifestations. Inasmuch as the "constitutional" taint or diathesis may be transmitted, we know not how, certain conditions in the individual may be regarded as consequent upon it and consistent with clinical observations. It is conceivable that the inheritance includes no more than "a molecular or chemical variation" in the central nervous system as the essential basis of the predisposition in hereditary neurasthenia. This implies "an exhausted or changed nutritional power"<sup>18</sup> and it may affect any special system or organ, as the central nervous system, liver or kidneys.

The foregoing considerations lead to a more precise conception of neurasthenia as a pathological condition, which may be the outcome of normal activities of the organic mechanism simply carried to excess, and conceivable as a subtle, and perhaps but slight, departure from a normal state. The restoration of cell contents to a normal state, following the physical changes observed by Hodge in normal fatigue, might continuously fail of being quite complete; and the "molecular or chemical variation" would then become established as the condition of "exhausted or changed nutritional power."

*Habit, Diathesis and Idiosyncrasy.*—There are other considerations, relating to the effects observed as accompanying the physiological use of the bodily mechanism, that are of great importance here. They include as an active factor, constantly and profoundly influencing all the activities of the mechanism, the law of use and practice, constituting the law of habit; they also include diathesis and idiosyncrasy. These modifying factors, or conditions, are nearly allied and are not always discriminated.

In regard to the law of habit, the moment the organic mechanism is put in use the effect of the law may be observed. In the reflex action of the organism it is a familiar fact that nervous action tends to follow certain lines of conduction, along sensory and motor nerves, and through transforming centres traversed before under like conditions; this constitutes the "nervous circle," and suggests the analogy of "paths" in the nervous mechanism. The well-known effect of practice in the muscular mechanism conforms to the law of use; and it must be taken for granted that analogous processes of practice take place everywhere in the nervous system and its accessory organs.

After any nervous action a changed condition remains by which a repetition of the action is rendered easier, and in all processes dependent upon the nervous system there are after-effects which find their expression in what is called "practice."<sup>19</sup> According to Wundt, the molecular changes in which this practice consists being unknown, it still claims material after-effects, which continue at first, but with no practice gradually fall away, and do not consist in a continuation of the function itself, but in facilitating its repetition; the remaining molecular effects are to be thought of as functional dispositions. This functional disposition to repeat organic processes constitutes the law of habit.<sup>20</sup>

<sup>15</sup> *Die Neurasthenie*, 1895, p. 110.

<sup>16</sup> *Journal of Nerv. and Ment. Diseases*, February, 1891.

<sup>17</sup> *Die Atrophie*, Pathol. H., pp. 51, 67 and 291, 295.

<sup>18</sup> Kowalewsky, loc. cit.

<sup>19</sup> See Radestock, *Habit*, trans. pp. 15, 16.

<sup>20</sup> For further discussion of this subject see my article, "The Mechanism of Insanity," *Ann. Jour. of Insanity*, April, 1891, p. 475.

The disposition must then be considered as consisting in a tendency of cell-contents to repeat the physical and chemical changes that occurred before, upon a repetition of the given stimulation. Thus use and practice are fundamental to the law of habit, and the conception of the "path of practice" in the nervous system implies ultimately the disposition of cells and cell-contents to repeat their processes in a such way as to constitute a habit; and through the effect of habit, there come to be paths of least resistance for the discharge of energy of nerve-cells.

The law of sensory and motor habit, in the lower centres of the mechanism, has a strictly physiological basis, and the process is a physiological one by which these neural habits are acquired, from the beginnings with the labored first efforts to the facility of the most automatic of reflex actions. As already stated a nerve-cell, or group of cells, receiving an impression is modified in some way, and retains an aptitude or disposition for reacting again in the same way. This being true, the same law applies to all the co-ordinations of centres, as groups of cells, which acquire dispositions to act together; whatever be their functions, they become associated in action, and the law of association is an extension of the law of habit that governs all neural activities. There is abundant evidence of such physiological association, not only between neural and muscular activities but between these and mental processes. This is true whether these processes are simply physiological and normal, or pathological in their nature. The effects of the laws of habit and association are most significant as to the evidence that during the acute stages of nervous and mental disorders, accidental changes in the play of nutrition, exhaustion, and toxic inhibition, disturb the wonted channels of nervous activity, and the currents may be arrested or diverted into new created paths. Such variations of molecular activity acquired by habit, also tend to remain as "after-effects" when the causes have passed away. The readiness with which such morbid neural habits may be acquired, and how intimate are the relations of mind and body in their influence upon each other, have been well shown by Tuke,<sup>21</sup> and by Weir Mitchell's descriptions of the mimicry of disease.<sup>22</sup> Prince<sup>23</sup> has also shown how these laws of habit and association should be extended, in his study of "associated neuroses and psychoses," in hysteria, neurasthenia, etc.

For these reasons the consideration of the constant influence of these laws of use, practice, habit, and association, should never be overlooked in the study of these disorders of physiological processes. The operation of these laws, when long continued, aids in inducing and perpetuating the changes, or "after-effects," which are conceived as something more than "dispositions" and not yet pathological, but as contributory and initial to such conditions and acting as "predispositions."

In normal conditions, native tendencies may become established in the individual by "education" of the nervous system through the operation of these laws. These are fundamental also to the theory of localization of cerebral functions, as the specialization of function of certain centres. The remarkable fact of the restitution of function after cortical injuries affords

reason for believing that there is the formation of new paths in the remaining centres, by which they become "educated" to duties which they did not originally possess.<sup>24</sup>

The central and peripheral mechanisms are therefore to be regarded as alike having specific functions, both native and acquired, both being manifestations of the law of habit and the important principle that our nervous system, in its elementary parts, becomes educated to such specific functions. The study of the law of specific nerve energy, and its relations to the law of practice and habit, furnishes further important evidence, not only of the plastic and changing character of our organic mechanism when put in use, but of the fixedness given by habit to modes of action long in use, alike in health and disease. This reveals the potent influence of habit in all organic activities, whether physiological or pathological.

Native tendencies, when acquired and established, may come to be transmitted, appearing as a part of the hereditary endowment; then there is a significant analogy between them and the recognized morbid "predispositions" which must have been largely acquired through the same laws. It is well, therefore, in seeking for the pathology of neurasthenia, to take account of habit as an element both of neural conditions and predispositions. The force of habit tends to establish disordered activities by the direct operation of the law of practice in the irregular action. In the evil effects of "disuse," and the consequent loss of power, there is probably never complete disuse, and the effects of vicious and deficient practice are manifestations of the primary law of use. The recovery from chronic invalidism, through resumption of right practice, finds sometimes striking examples, as in "mind-cure," hypnotism, etc. These laws of use, practice, habit, and association in physiological processes, also help to an explanation of the clinical phenomena of apparent resistance to nutrition in confirmed neurasthenia. They cannot be ignored as contributive, and they are, perhaps, sometimes the sole cause of the underlying molecular variations in the nerve-cells, whose exhausted and changed nutritional power is thus maintained.

The relations of the diatheses to neurasthenia have been noted; great interest also attaches to the study of the more defined and limited tendencies known as idiosyncrasies,<sup>25</sup> which are innumerable in variety; everybody has them, and they are but rarely discriminated unless made prominent by their singularity and inconvenience. The well-known forms of idiosyncrasies against certain drugs, articles of food, poisons, etc., commonly regarded as constitutional and hereditary, are known to be sometimes suddenly acquired,<sup>26</sup> when there had been previous toleration, for example, in the use of chloral, quinine, tea, tobacco, etc. The changes in the organism induced by drug habits are of equal interest.

The relations of all these phenomena to molecular and chemical variations finds explanation in the newer views as to the physics and chemistry of cell activity. It is probably not too broad a conception of the law of habit to regard it as capable of inducing, in this way, and certainly as contributory to, both diatheses and idiosyncrasies. The views generally held of these

conditions or results of activity lead us to regard them as representing tendencies to structural change. Habit, diatheses, and idiosyncrasy, may be characterized as principal elements of variation in the organic mechanism. In the direction of pathological change they describe conditions initial and antecedent to it, being themselves not structurally demonstrable, except as to some congenital peculiarities classed as idiosyncrasies. Habit, though primarily normal, must, as a functional disposition to repeat organic processes, increase the persistency of the other two conditions. Diathesis is regarded as having always a pathological interpretation, and as being a *proclivity* to some peculiar type of disease; it is both hereditary and acquired, and carries the idea of persistency, — but it is curable, and having a toxic element conforms to the conception of a molecular and chemical variation. Idiosyncrasy is assumed to depend upon some structural change, usually hereditary and not always tending to disease. But being sometimes acquired, and often existing as a susceptibility to toxic influences, this implies again the occurrence of variations, of the character already mentioned, that may be initial to pathological change. And these implied variations serve to account for the manifestations of an exhausted or changed nutritional power.

While our present knowledge of the pathological conditions in neurasthenia is unsatisfactory, even with the most logical of inferences, we have to study, with all the more care, the recognized influences at work in the genesis of this nervous disorder. In the study of neurasthenia it is of special importance to note that such individual tendencies and idiosyncrasies may become emphasized with the lowered tone of the nervous system, and increased susceptibility to toxic influences.

### PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

BY HAROLD C. FERNST, M.D.,  
Instructor in Bacteriology at the Harvard Medical School.

(Continued from No. 3, page 58.)

CASE 21. Boston. Date of admission, February 2, 1891. Service of Dr. E. H. Bradford. Born in Sweden, thirty years old, single, machinist. Father died of "nervous disease," at fifty-eight. Disease has lasted for twelve years. At that time there was an amputation of the great toe of the left foot and two fingers of the left hand, for the same trouble as is now present. General health good; no loss of flesh; is fairly well developed; good strength and nutrition; fair appetite and sleep; heart and circulation negative; is troubled with dyspnea; urine acid, 1023, normal color, no albumen; abdomen negative. Present disease commenced as a little pimple, two years ago. It heals apparently, and then breaks out again.

Examination showed an irregular-shaped ulceration of the skin on the left foot, over the distal extremity of the first metatarsal bone, unhealthy granulations covering an area the size of a half dollar, and involv-

ing the stump resulting from the amputation of the great toe twelve years ago.

February 5th. The discharge is quite abundant, sero-purulent, almost of a gelatinous nature.

February 8th. Dose, .0012 gm.

April 9th. Dr. Sumner reports considerable improvement in all the signs, that is, that they are less marked, except that the vocal resonance is still decidedly increased. The ulceration of the toe is about two inches long and three-quarters of an inch broad, kidney shape; granulations are red, bleed easily, and present a hob-nail surface. Considerable discharge. Patient desires to go home, and is discharged, relieved.

*Summary.* — Number of injections, 21; amount used 127.6 mg.; highest dose, 12 mg.; highest temperature, 103.8°, after the fourth injection of 4.2 mg. Discharged, not relieved. (See Dr. Sumner's report of April 9th.)

CASE 22. Somerville. Admitted January 8, 1891. Service of Dr. C. B. Porter. Born in New England, forty years old, married, clerk. Excellent health until two years ago. Disease began with occasional pain in the right knee. General health good; in appearance well developed; fair strength; some emaciation; good appetite and sleep; temperature 98.4°; pulse 84; abdomen negative.

Two years ago had occasional pain in the right knee with some stiffness. In a few weeks noticed an enlargement of the joint, with pain, which was especially marked at night, and most severe on either side of the patella. The stiffness of the joint increased until six weeks ago, when he was obliged to use crutches. Eighteen months ago, found some small tumors in and below the right groin. Twelve months ago, the fingers of the right hand stiffened, and the patient noticed a swelling on the further side of the ribs, just above the joint. Has lost much flesh and strength in the last few years.

Examination shows the right knee slightly flexed, some sub-luxation. The joint shows general enlargement; decidedly resistant; small area of fluctuation on either side of the patella. Motion is limited to a few degrees of flexion and extension. Passive motion is not painful. No distinct tender spot. The patella is movable. The right groin and Scarpa's triangle is filled with moderately enlarged glands. The under-surface of the left forearm, just above the wrist, shows a prominent area, two and one-half inches by one and one-half inches in measurement, soft, fluctuating, not tender, the skin not reddened or indurated. The flexor tendons are evidently involved. The wrist circumference is six and one-half inches. The knee, above fourteen inches; over the patella, fifteen; below thirteen.

January 9th. Dose, .0015 gm. Chill at 8 p. m. Increased pain and swelling in the wrist, increased pain in the knee.

April 8th. Bacilli in the discharge No. 1, appearing in masses. Treatment omitted, for the purposes of this paper.

*Summary.* — Number of injections, 30; amount used 203.5 mg.; highest dose 16.8 mg.; highest temperature 103.6°, after the first injection of 1.5 mg. Discharged, not relieved; although power of left wrist and fingers is much increased and almost normal and there was a gain of eight pounds in weight. Is this a case of uneven activity of the material?

May 11th. Reported as being much worse. Has

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1891.

<sup>2</sup> Hutchinson, op. cit.

not left the bed for two weeks. Has a cough, hoarseness of voice and some expectoration.

**CASE 23.** East Cambridge. Admitted January 6, 1891. Service of Dr. F. C. Shattuck. Born in Ireland, eighteen years old, housework. Good family history; always well and strong. Disease began fifteen years ago, with a swelling of a cervical gland on the left side. Menstruation has been absent since coming to this country. Well developed; good strength; well nourished; good appetite and sleep; heart and circulation negative; temperature 100°; pulse 98; respiration 25; urine normal, acid, slight trace of albumen, sediment shows a little pus, a few vaginal or bladder cells; abdomen negative. At three years of age had an enlarged gland in the cervical region on the left, which was incised. Since then, from time to time, other glands in the neck have become swollen and suppurated, as shown by old cicatrices.

Examination shows a hard, indurated mass of swollen glands, under the angles of the jaw, and several large, red cicatrices of different ages on either side of the neck, and several old scars about the left clavicle. Examination was otherwise negative.

January 7th. Dose, .001 gm. Weight 138 pounds. No results noted.

March 7th. Dose, .012 gm. No reaction after.

**Summary.**—Number of injections, 22; amount used, 185.8 mg.; highest dose, 19.6 mg.; highest temperature, 104.2°, after the third injection. Discharged, relieved. The cervical glands had cicatrized, no discharge, and general condition better. A gain of eight pounds in weight.

**CASE 24.** Boston. Admitted January 5, 1891. Service of Dr. F. C. Shattuck. Born in Ireland, forty-one years of age, married, fish peddler. Family history negative; of alcoholic habits. Chancre ten years ago. Rheumatism nine years ago. From eight to ten years has had every winter a hard cough. Debilitated appearance; poor strength and nutrition; fair appetite and sleep; skin normal, except on the hand; heart and circulation negative; pain about the shoulders; urine normal, acid, 1015, no albumen; right inguinal hernia; about one-half of the glands penis gone. Disease began two years ago, as the result of a cut from a bottle on the back of the right hand. The wound did not heal readily, and soon broke out in small white places and black specks. Has been treated in various out-patient departments—scraped, cauterized, etc., but always to return. Drs. Post, Bowen and White give the diagnosis of tuberculosis. Examination of the right hand shows a reddened, somewhat scaly, atrophied patch on the back, covering nearly the whole, with much induration.

January 7th. Dose, .0012 gm. No special general reaction. The hand is slightly swollen, increased hyperæmia, covering back of hand to the phalanges.

March 19th. Dose, .012 gm. Discharged for profanity.

**Summary.**—Number of injections, 23; amount used, 208.4 mg.; highest dose, 15 mg.; highest temperature, 100.8°, after the sixth injection of 7.2 mg. Discharged, not relieved.

**CASE 25.** Shelburne Falls. Admitted December 29, 1890. Service of Dr. J. C. Warren. Born in Vermont, fifty-two years old, married, furniture-dealer. Disease began, about a month before admission, with the appearance of a small spot on the left side of the tongue. General health fair; appearance well devel-

oped; fair strength and nutrition; good appetite; heart and circulation negative; temperature 99.8°; pulse 100; slight cough in the morning.

Physical examination shows the existence of a spot on the left side of the tongue, which has enlarged, with pain, until it has reached the size of about one inch by two-thirds of an inch; it is near the tip, and the under side is apparently involved. On the under side there are several small, white ulcerations of like appearance to the side. A piece removed under cocaine, and sent to Dr. Whitney, shows bacilli and giant cells. Examination of the lungs, by Dr. Shattuck, showed fine, moist râles, heard on cough, both in the supra- and intra-clavicular region on the right side. The patient never knew he had any trouble in the lungs. A small abscess, about two by two centimetres, at the left margin of the anus on the left side, fluctuating and tender, and about one week old.

January 1, 1891. Dose, .0008 gm. Good sleep; bacilli in the sputum No. 8; tongue swelled and became tender; abscess near the anus was sore, swelled up and burst at eight P. M.

April 15th. Dose, .012 gm. Treatment omitted for a time.

**Summary.**—Number of injections, 45; amount used, 380.8 mg.; highest dose, 12 mg.; highest temperature, 101.4°, after the first injection of .8 mg. Not relieved.

April 29th. General condition good; weight, 149 pounds; bacilli in sputum, No. 7; tongue less swollen and less active than on 14th; no apparent discharge from it. Physical examination shows very slightly diminished resonance and a few medium and fine râles to the second rib on right below apex, a very few fine râles upon hard cough below the second rib; back, no signs. Discharged, not relieved. The tongue seemed to be certainly in a less active state at last examination. At first it apparently made very active steps towards healing, diminishing in size of nodule and infiltration about it.

**CASE 26.** Boston. Admitted December 9, 1890. Service of Dr. Barrall. Born in Ireland, single, horse-shoer. Had pleurisy two years ago. Sanitary surroundings good. Disease commenced two weeks ago, before admittance. General health fair; appearance anæmic; fair strength and nutrition; good appetite and sleep; skin, heart and circulation negative; suffers pain in the lesion; had an abscess of the ankle; diagnosis of tuberculosis. Was in the City Hospital last winter with a fracture of both bones of the left leg. Discharged on November 24, 1890. (Entered about the middle of November, for an injury to the ankle, two weeks old. In two days the plaster circular removed and a new one applied. Out on crutches.) The night following the new application, had great pain in the foot and ankle, and on the following two days. Patient had the plaster removed, and applied tincture of iodine, and then came to the hospital. Urine was turbid with urates, 1030, very acid, no albumen.

Examination showed the lower right leg swollen, tender and red, most marked in the foot, and extending nearly to the knee, but to a less degree. The treatment was side-splint and rest in bed.

January 4, 1891. General condition fair; appetite and sleep good; slight pain about the ankle. The same discharge persists about the ankle. There is much thickening.

January 10th. Dose, .0008 gm. The treatment begun at the patient's request. The circumference of the ankle, about one inch above the os calcis, eleven and one-quarter inches.

Examination of the discharge every other day. Bacilli were found once.

Opening below the external malleolus is closed in. There is now motion in the joint. The opening below the internal malleolus filled with healthy granulation. Is to be dressed every four or five days. Thomas's knee- and wire-splint for ankle. Discharged, relieved.

*Summary.*—Number of injections, 7; amount used, 32 mg.; highest dose, 10 mg. (Chart lost and temperature not obtainable.) Discharged, relieved. The bacilli were found once, and then not again.

CASE 27. Boston. Admitted December 31, 1890. Service of Dr. Bradford. Born in Boston, nine years old, Irish parentage. Poor appearance, strength, nutrition, appetite and sleep; heart and circulation negative; abdomen negative; no enlargement of the glands. Entered with sensitive left hip, and permanent flexion of 50°; no motion in the joint. Leg held by muscular spasm; abduction of 20°; no sign of abscess.

February 20, 1891. Dose, .0004 gm. General condition poor; emaciation marked; hip sensitive; abscess on the anterior surface of the thigh; sleeps much, but is fretful.

April 8th. Dose, .0048 gm. Treatment omitted for a time.

*Summary.*—Number of injections, 20; amount used, 60.5 mg.; highest dose, 4.8 mg.; highest temperature, 105°, springing from 97°, after the seventh injection of 2.4 mg., a rise of eight degrees. Discharged, relieved. General condition much improved; discharge from hip less.

CASE 28. South Boston. Admitted December 16, 1890. Service of Dr. Bradford. Born in Boston, eight years old, single, school-girl. No family history given. Disease commenced, May, 1890. General health poor. Poorly developed; poor strength, nutrition, appetite and sleep; lungs normal; abdomen normal. She has a corneal ulcer of the left eye. Was in the hospital in August, 1890; returned with the left hip flexed at 30°. No motion in the hip. Abscess in the left iliac fossa.

February 20, 1891. There is profuse discharge from sinus in hip. Motion shows flexion about 90°, abduction about 15°, rotation limited one-half. Glands enlarged on the left side of the neck, with a moderate amount of swelling. An old cicatrix just above the angle of the jaw. Ulcer of the cornea of the left eye, with marked photophobia and discharge.

February 20th. Dose, .0004 gm.

March 18th. Dose, .0048 gm. Discharge from the sinus much less, and of thinner consistency. A visible increase of flesh; the eye improving.

April 8th. Dose, .006 gm. Treatment temporarily omitted.

*Summary.*—Number of injections, 23; amount used, 83 mg.; highest dose, 6 mg.; highest temperature, 103°, after the fourth injection of 1.5 mg. Discharged, much relieved. Eye well. Cervical glands diminished. Hip less sensitive, and discharge much less. Is about on crutches.

CASE 29. Boston. Admitted November 12, 1890. Service of Drs. Gavin and Bradford. Born in Poland, twenty years old, single, laborer. Speaks no English.

Typhus fever several months ago; since then has had pain in the wrist. Below the medium size; of good strength, nutrition, appetite and sleep; urine normal, very acid, 1020, no albumen. Enlarged wrist at the end of the radius, and apparently some of the carpal bones are enlarged. On the palmar surface, directly over the carpo-radial joint, is a granululating surface, which is about the size of a quarter-dollar, that looks as if it was the remains of an old ulcer. No pain or tenderness, and the fingers move freely.

December 14th. Incision over the lower end of the radius made, about four inches long. The end of the radius found soft and carious. One and one-half inches of the lower end was excised, and the bone cured.

January 1, 1891. General condition good.

January 4th. Dose, .0008 gm. Slight headache; nausea; chill. Discharge increased in quantity; no bacilli in discharge.

April 3d. Pulse and temperature normal; no pain or tenderness; still in the hospital.

*Summary.*—Number of injections, 7; amount used, 20.4 mg.; highest dose, 6 mg.; highest temperature, 101.8°, after the third injection of 2 mg. Discharged, not relieved. (Dr. Bradford considers condition of wrist on opening, on March 27th, as evidence of improvement. Is doing extremely well now.)

CASE 30. Dedham. Admitted January 5, 1891. Service of Dr. J. C. Warren. Born in Ireland, thirteen years old, single, school-girl. Family history good. Disease began five months ago, with a swelling of the thumb. General health good; well developed; poorly nourished; anæmic; good appetite and sleep; heart and circulation negative, and suffers from pain in the lesions; urine slightly pale, acid, 1014, no albumen; abdomen negative. Five months ago noticed that the right thumb was growing larger. A little later a swelling appeared between the fourth and fifth metacarpal bones at the distal end; slowly increased in size, accompanied with a slight amount of pain at times. In two or three months a sore came on the thumb, which repeatedly discharged and healed over again.

Physical examination negative. The right thumb is considerably enlarged, the skin red and indurated; but the thumb is not tender; one small ulcerated portion the size of the little finger-nail. Motion in the terminal joints is much impaired; between the fourth and fifth metacarpals an indurated mark; the skin not red or tender on pressure. At the base of the third toe of the left foot there is a thick, reddened area, with a crust one cubic centimetre in diameter.

January 7th. Dose, .0006 gm. A slight increase of temperature; no local change.

April 7th. Treatment omitted. Thumb amputated by Dr. Beach.

*Summary.*—Number of injections, 28; amount used, 125.4 mg.; highest dose, 7.8 mg.; highest temperature, 103.8°, after the eleventh injection of 4.8 mg. Discharged, not relieved by treatment.

April 29th. Patient at Convalescent Home at Waverley. General condition good.

CASE 31. Charlestown. Admitted December 29, 1890. Service of Dr. C. B. Porter. Born in Washington, twenty-three years old, single, shoemaker. Family history negative. Former history good. Date of commencement of the disease, five years ago; result of a bullet-wound. General health good; well devel-

oped; good strength, nutrition and appetite; fair sleep; normal skin; heart and circulation negative; pain in left elbow; stools negative; abdomen negative. Recovered from the bullet-wound, with perfect motion in the right elbow. Five months ago he perceived stiffness and pain in the right elbow, with a gradual limitation of motion. Swelling appeared on the outside of the joint about one month later; and shortly after, a sinus formed, discharging a sero-purulent fluid. This discharge has persisted.

Examination shows the right elbow region symmetrically swollen, circumference, twelve and one-half inches; of the left elbow, eleven inches. Joint immovable, and fixed at  $140^{\circ}$ , with the very slightest amount of flexion. Pronation and supination not possible. Swelling hard, fairly smooth, and not tender. Corresponding with the head of the radius, there is a sinus, which allows the probe to enter for three inches. There are two smaller sinuses, one above and one below. These discharge a small amount of grayish-yellow, watery fluid. Examination of the chest by Dr. Tarbell shows slight dulness at the left apex, harsh respiration a few fine, moist rales, with slightly increased voice-sounds over the dull area. Examination of the discharge from the sinus, negative.

January 1, 1891. Dose, .001 gm., followed by increased pain in the arm. On the next day the arm slightly fuller at the elbow, and the amount of discharge slightly increased in the night.

January 22d. Fluctuation at the elbow. Operation; ether. Incision showed no pus that could be evacuated; but the whole tissue was boggy and oedematous. Probe could pass into the joint, which was open and full of granulation.

February 7th. .0084 gm. Sent out because of insubordination. Abscess at the elbow broke with very much discharge.

February 24th. Returned for operation under ether by Dr. Porter. Excision of the elbow. Bones of the forearm especially disorganized. No new growth of tubercle could be found. All the sinuses were cured.

March 1st. Main wound closing. Sinuses granulating well; no pus present.

March 15th. Dose, .006 gm. Sent out for insubordination.

*Summary.*—Number of injections, 22; amount used, 93.4 mg.; highest dose, 8.4 mg.; highest temperature,  $104.2^{\circ}$ , after the fourteenth injection of 6.6 mg. Discharged, not relieved.

(To be continued.)

## THE CONDITION OF BODIES LONG BURIED.

BY WALTER R. HOLMES, M.D., WATERBURY, CONN.

THE old cemetery in Waterbury, Conn., containing bodies buried from 1709 to 1867, having fallen into great neglect, and being situated near the centre of the city, was finally, by a vote of the authorities, made the site for a public library building. Disinterment of many of those who were buried there was begun on April 27, 1891. As opportunity rarely occurs on so large a scale for observing the condition of bodies buried so many years, I will state that of those I saw disinterred.

The first was that of a lady, thirty-eight years of age, who was buried in 1741. After digging some

seven feet through a light sandy soil, a very thin layer of a dark-colored earth, very moist, was reached, which was what was left of the coffin and flesh and bones. No structural remnants were to be seen in this. None of the bones were to be found except some of the cranial bones, separated at their sutures, a few teeth, and considerable brown hair covering the parietal bones. The frontal bone was fairly perfect, showing clearly the orbits. Both parietal bones were found, nearly whole, and covered thickly with brittle brown hair. Parts of the upper jaw, with sound, excellent teeth still imbedded in them, still existed. The sternal end of one clavicle and the bodies of a few of the upper vertebrae, with one lamina of a dorsal vertebra, were the only remaining bones. All the bones were wet and heavy—much moister than the adjoining soil. The only traces of the coffin were two small pieces of wood, preserved by the nails that had passed through them, and rust-stained. On breaking one of them in two, the substance of the nail was seen to have disappeared, but its form was indicated by a long square tube of iron-rust. This cavity was filled with a watery fluid. The long persistence of the hair, showing apparently nearly its original color, seemed strange when nearly all the solid parts of the skeleton were gone.

The adjoining grave contained the remains of the husband, who died in 1759, aged forty-eight years, and was fully eight feet deep. This skeleton was in a far better state of preservation than the wife's. The femora, humeri, one tibia, the atlas and the entire skull (part of the face having been broken while digging it up), were found. The long bones being very heavy and almost dripping with moisture, though the soil was very dry. In both cases it was easy to see where the grave-diggers one hundred and fifty years ago had disturbed the earth; and the contrast between the earth that had been dug up and that adjoining it was marked.

Another grave that was of interest contained the body of a man aged one hundred and one, who died in 1866, and of his wife aged eighty-nine, who died some fourteen years before. His was one of the most recent burials, and the box and the enclosed coffin, though rotten, retained their shape fairly well. When it was opened the lower extremities could be seen their whole length, the trunk and head being covered with earth. The tarsal and metatarsal bones were well preserved and also the phalanges of the toes. The head was well covered with hair on the back, and a few scattered hairs were seen opposite the middle of the forehead in front, as is so often seen on bald heads. There was a heavy beard still adhering to the chin, and a black neckcloth with a tie in front in good preservation. There was no evidence of so great age in the joints, whose surfaces were smooth and normal. The neck of the thigh-bone left the shaft at a less acute angle than is seen in bones of younger persons, but the difference was not so marked as is often seen. The jaws of the wife were toothless, the lower jaw consequently very shallow. There was in front a very sharp-edged ridge inclining backward towards the mouth; and the ramus left the body at a very oblique angle; its end would hardly rise more than three-fourths of an inch from the horizontal if the jaw were laid on a table.

The roots of plants—there are now very few trees in the cemetery—were in most cases closely intertwined among the bones, holding them snugly together and resisting their being lifted, even in the deepest

graves. The skulls were in the older graves far better preserved than the rest of the bones, sometimes being about the only parts left. Teeth were found nearly perfect, and many of the older skulls had complete and polished sets of teeth even at an advanced

and stapes, white and perfect. It seems strange that this very delicate little bone, the smallest in the body, could resist decay for one hundred and thirty-six years. The teeth in the upper jaw were all gone, but there was one large empty socket on the left side, from which a tooth probably dropped during disinterment. In the lower jaw were three teeth, one partly and one badly decayed. In the side view of the skull it can be seen that the forehead was not of unusual height, but the great length of the skull is remarkable. A little wisp of white hair is adherent to one side of the vault of the cranium. The sagittal suture and the upper part of the lambdoidal have disappeared except a very few traces, but for half an inch above the nasal bones remains of the suture that unites the two halves of the frontal bone are distinctly visible.

The axis has a peculiarity which may be due to ossification of the soft parts in old age. The articulating surface on the anterior face of the odontoid process is continued for nearly three-eighths of an inch above the rest of the process, forming a convex projection above it, like a shield or battlement. It is high enough to project considerably above the upper surface of the atlas when these bones are articulated, but during life the thickness of the cartilages

covering the joints must have raised the atlas up even with the top of this shield. In the median line of the anterior arch of the atlas are two somewhat similar shields of bone or exostoses, lengthening the articular surface on the inner side of the arch both upward and downward. I saw nothing peculiar in the other vertebrae, but in two lumbar vertebrae of another man seventy-seven years of age, there was a large and broad concave, hook-shaped projection from the side of the body of the lower vertebra, into which was received a convex exostosis from the lower edge of the body of the vertebra immediately above. This must have completely prevented any motion between

age. One skull had a complete and perfect set except as they had been worn down on their grinding surfaces by many years' use on what was perhaps coarse food.

Another skeleton was that of a minister, eighty years of age, who had been buried for one hundred and thirty-six years, and who is said to have been the principal man in the town during his life. The skull and many of the long bones, especially the femora and humeri and many of the vertebrae were in most excellent preservation. The skull was perfect, even the delicate turbinated bones and thin walls of the orbit being whole. The skull is a remarkable one and is shown from two points of view; the skull of a mound-builder from the West being shown by its side for the sake of the contrast. It will be seen at once that the mound-builder's is an extreme example of the brachycephalic type, and the white man's of the dolichocephalic. The extreme length backwards from the foramen magnum is remarkable, by far the greater part of the occipital bone being nearly horizontal, and taking a sharp turn upward nearly at right angles at the occipital protuberance. The distance from the posterior edge of the foramen to the protuberance is two and a half inches; from the anterior edge to the alveolus of the incisor teeth is three and a half inches, so that the centre of the base of the skull is precisely at the anterior edge of the foramen. The hook at the lower ends of the inner pterygoid plates is very well developed, and the outer plates are very large in size, and at their base are two foramina on each, piercing the external plates from side to side. I have one other skull with the same excessive development of the external plates. The same peculiar formation is spoken of by Dr. Thomas Dwight in the *JOURNAL* of June 1, 1891, p. 555. The "foramen pterygospinosum" was present in my specimen, and another one nearly, but not quite complete, directly behind it. I found in one ear the malleus, incus

the two bones. The upper pair of genial tubercles on the lower jaw of the skull, shown in the cut, are grown together into a long, sharply-pointed process which projected directly back into the tissues of the floor of the mouth.

The other skull is considered to be that of a mound-builder. It is almost the exact counterpart of the one figured in Squier and Davis's "Monuments of the Mississippi Valley" or Volume I of "Smithsonian Contributions to Knowledge." In the book the skull figured is said to be the only one known at that time to be a mound-builder's, and to have been exhumed from a mound made by that people. The skull shown in the cut in the JOURNAL is very white and quite brittle, the bones having lost nearly or quite all their animal matter. It is evidently of great age. It is owned by a gentleman in this town who has several old Indian skulls, including some found in Connecticut, and who is strongly of the impression that the skull shown here was bought from the collection of one of the writers of "Monuments of the Mississippi Valley," having been found after that book was published.

The bones of the bodies buried more recently, within forty or fifty years, are much better preserved. In many of these all of the bones were found, even the hand and foot bones, which seem to be among the first to disappear. In one case a silk dress was found, quite perfect. In the hair of female skulls the bone combs with which the hair was secured in the knot at the back have lasted very well. In graves fifty years old or thereabouts considerable portions of the coffins are found, but the coffin has always been crushed in by the pressure of the earth, and large portions of them have disappeared. Coffin plates last well and are legible even when many years old. In the graves twenty-five or thirty years old the coffin and its enclosing box are both found, though they are both considerably decayed.

## Medical Progress.

### RECENT PROGRESS IN THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M. D.

#### CORROSIVE SUBLIMATE AS A DISINFECTANT.<sup>1</sup>

EXPERIMENTS published by Dr. A. C. Abbott, made in the pathological laboratory of the Johns Hopkins Hospital, have a very practical bearing upon the value of corrosive sublimate as a germicide, and the results of these experiments lessen the high estimation in which this agent has been held by most investigators.

Dr. Abbott selected the staphylococcus pyogenes aureus for a series of experiments as to germicide power, in consequence of the importance of this subject to the surgeon. The tests hitherto made upon corrosive sublimate as a disinfectant have agreed in giving to it the first place in the list of these agents.

One method commonly employed in testing the value of any chemical substance as a disinfectant is to expose organisms dried upon bits of silk thread to its action for different lengths of time, and then, after removing and carefully washing the threads in water and alcohol, to place them in nutrient media at a favorable temperature and notice if any growth results from them. If no growth appears, the disinfection was presumably successful. Another common method is to mix fluid cultures of organisms with the disinfectant, and, after different intervals of time, a portion is taken from the mixture and placed in nutrient media just as in the other method.

Now, in both of these methods it is easy to see that unless special precautions are taken a minute portion of sublimate may be carried along with the thread or drop into the medium which is to determine whether or not the organisms on the thread or in the drop still possess the power of growth. For organisms in their normal condition, — that is, those that have never been exposed to the action of a disinfectant, — the amount necessary to restrain growth, for certain disinfecting agents, is very small indeed; and for those organisms which have previously been exposed for a time to such agents, Geppert shows it is very much less.

In the case of the organism we are considering, Dr. Abbott finds the amount of sublimate necessary to prevent the growth of perfectly normal staphylococci to be one part of sublimate in 75,000 parts of the ordinary peptone bouillon, or 200,000 parts of bouillon without peptones. So that, if organisms which have been once exposed to stronger solutions of this salt (1 to 1000) require less than these amounts to inhibit their growth, it is plain that special precautions must be taken to prevent transportation of this minute trace into the nutrient medium which is to demonstrate whether or not the organisms are capable of development. The author gives in detail a series of experiments, and draws the following conclusions:

That under the most favorable conditions, a given amount of sublimate has the property of rendering inert only a certain number of individual organisms, — that is to say the process is a definite chemical one taking place between the protoplasm of the individual bacteria and the sublimate in the solution.

The disinfecting activity of the sublimate against organisms is profoundly influenced by the proportion of albuminous material contained in the medium in which the bacteria are present. It was found that the relation between the golden pyogenic staphylococci and sublimate is not a constant one, organisms from different sources and of different ages behaving differently when exposed to the same amount of the disinfectant for the same length of time.

Many of the results of previous experimenters, who have assigned to corrosive sublimate more powerful disinfectant properties against the staphylococci pyogenes aureus in cultures than the observations reported to this paper indicate, are attributable to the neglect of certain precautions now recognized as essential to the proper conduct of such experiments. At the present stage of our knowledge in this direction it is plain that for use in surgical practice the solutions of corrosive sublimate do not possess all the advantages hitherto attributed to them.

In regard to the employment of sublimate solutions upon wound-surfaces it is plain that there exists at least two serious objections: First, the albumen of the tissues and fluids of the body tends to diminish the strength of, or, indeed, renders entirely inert, the solution employed; and, second, the integrity of the tissues is materially injured by the application of this salt. The first objection cannot be met with certainty, for the surgeon possesses no means by which he can determine the amount of albuminous material with which his solutions are to come in contact, and in any case this large amount of albuminous material is an almost insuperable obstacle to complete disinfection with sublimate. He is, therefore, never in a position to say, *a priori*, that his efforts at disinfection of the wound are or are not successful.

<sup>1</sup> Johns Hopkins Bulletin, No. 12.

During the past two years we have had sufficient evidence to lead us to believe that the normal tissues and fluids of the body possess the power of rendering inert many kinds of organisms which may have gained access to them. This function is therefore diminished, or, indeed, may be quite destroyed, by any agent which brings about alterations in the constitution of these tissues. We know that just such changes as those to which we refer are known to follow the application of sublimate solutions. It is plain, then, if we bring about in these tissues a condition of superficial necrosis,—the condition following upon the application of sublimate,—they are much less able to resist the inroads of infectious organisms than they would have been had they been left in their natural condition.

As a disinfectant, in the strict sense of the word, there are, perhaps, few substances which possess the property in a higher degree than does corrosive sublimate, but at the same time there is nothing which is employed for this purpose that requires greater care in its manipulation in order to obtain its best results, than does this salt. In practice its action is influenced by a number of conditions which it is difficult, if not quite impossible, to control.

For these reasons we seem hardly justified in continuing to give to it the first place in the list of substances which may be employed practically for the purpose of rendering harmless, materials containing the germs of infectious maladies.

#### ANTISEPTIC TREATMENT OF TYPHOID FEVER.<sup>2</sup>

In a lecture on this subject, at King's College Hospital, Dr. Yeo has called attention to the progress that the idea of an antiseptic treatment of typhoid fever is making amongst physicians in all parts of the world. He is unwilling in the present stage of our knowledge, to put too much stress upon any particular manner of carrying out this idea, as we have probably not arrived at the very best means for doing so. What he says about the application of the idea of antiseptics in typhoid fever by various practitioners is of interest.

Professor Petresco, Bucharest, has borne valuable testimony to the efficacy of naphthol. He had previously experimented with carbolic acid, salicylic acid, turpentine, benzoic acid, kairin, calomel, corrosive sublimate, and boric acid without any very favorable results. He then tried a saturated solution of sulphide of carbon, with which he was much better pleased; and lastly he tried naphthol, fifteen grains three times a day, and had results more favorable than with any other remedy; the rate of mortality was reduced, and the course of the disease favorably modified.

Dr. Clarke, of Bristol, used hydro-naphthol in five cases of typhoid fever, and all did well. It soon stopped the diarrhoea, and the stools lost their offensive odor. He gave from three to four grains every two hours, until the diarrhoea was checked, and then every three hours so long as there was fever.

Dr. Treissier, of Lyons, prefers α-naphthol for producing intestinal antiseptics in typhoid fever. He gives it in six-grain doses, combined with salicylate of bismuth, and he, at the same time, promotes free diuresis by cold water enemata. He also gives enemata of quinine and cinchona as an "antithermic tonic." He observed that as soon as intestinal antiseptics was established the urine became green, the temperature fell, the albuminuria disappeared, the spleen dimin-

ished in size, and the tongue became remarkably moist. Convalescence was very rapid. He considers that naphthol acts by sterilizing the bacterial products in the intestine.

Dr. Schwartz has demonstrated that naphthalene administered internally diminishes the number of bacilli in faecal matter in the proportion of one-third to one-fourth. When its administration is discontinued, this proportion increases again. But naphthalene is not so safe or suitable an intestinal antiseptic as B-naphthol or x-naphthol.

Dr. W. H. Thompson, of the Roosevelt Hospital, New York, is an advocate of intestinal antiseptics in typhoid fever. He looks carefully after the food administered; he never gives milk undiluted, but always mixed with an equal quantity of lime water. He objects to beef-tea as setting up gastro-intestinal fermentation. He gives, also, ten grains of saccharated pepsin with ten minims of dilute hydrochloric acid every three hours, sometimes both medicines every two hours. He regards these as the best agents for the purposes of intestinal antiseptics.

Many physicians have recorded their approval of an initial laxative, and no doubt it is well, as there is no diarrhoea, to begin with one; we shall then have less hesitation in keeping the bowels quiet afterward. Indeed, it has been said, that "purgation and antiseptics are, to some extent, interchangeable terms." An aperient expels the poisonous ptomaines and other decomposing substances from the intestinal canal, and, if given in the early stages, may actually prevent subsequent serious diarrhoea. But the use of aperients, to be perfectly safe, must be limited to the first ten or twelve days of the fever, the great risk attending their use in the later stages is the possibility of the existence of deep ulceration in the ileum, and, in that case, an aperient may mean the difference between life and death to the patient. At that period of the disease intestinal antiseptics can only be safely secured by the use of intestinal antiseptics.

#### ONTIMENT FOR HEMORRHOIDS.<sup>3</sup>

R	Hydrochlorate of cocaine . . . . .	grs. xvj.
	Sulphate of morphine . . . . .	grs. v.
	Sulphate of atropine . . . . .	grs. iv.
	Powdered tannin . . . . .	grs. xvj.
	Vaseline . . . . .	3j.
	Essence of rose . . . . .	q. s.

Make an ointment and apply to the affected parts after each movement from the bowels. It is necessary to have the discharges of soft consistence.

#### HYDROCHLORATE OF PHENOCOLL, A NEW ANTIPYRETIC AND ANTI-RHEUMATIC.<sup>4</sup>

This substance appears in the form of a white powder soluble in water. It is a compound of phenetidine and seems to be similar in action to antipyrine. Fifteen grains of phenocoll reduces the temperature about as much as would be accomplished by twenty-two to thirty grains of antipyrine or about fifteen grains of phenacetine. It has analgesic properties in doses of seven to fifteen grains.

#### VEGETATIONS ON THE GENITALS.<sup>5</sup>

R	Acid, salicylic . . . . .	grs. viij.
	Acid, acetic . . . . .	5j.

Apply to the warts with a camel's-hair brush once or twice a day.

<sup>2</sup> Journal of the American Medical Association, 1891.

<sup>3</sup> Deutsche med. Wochenschrift, No. 15, 1891.

<sup>4</sup> Medicines Modernes, 1891.

<sup>5</sup> Lancet, Nov. 3, 1891.

METHODS FOR THE ADMINISTRATION OF AMYL-HYDRATE.<sup>6</sup>

A teaspoonful of amyl-hydrate may be taken at night in a small glass of beer. It should be stirred for several minutes to insure solution. Or, of the following, one half may be taken at night.

R Hydrate of amyl	. . . . .	3i.
Water	. . . . .	
Orange-flower water	. . . . .	ss 3ij.
Syrup of bitter orange	. . . . .	3j.

It is necessary to remember that amyl-hydrate dissolves slowly in water and beer (one part to eight).

Amyl-hydrate may also be taken in capsules, each one containing one-quarter of a drachm; three or four of these may be used for a dose.

AN ADDITION TO THE THERAPEUTICS OF EPILEPSY.<sup>7</sup>

Almost countless drugs and combinations of drugs have been used in the treatment of epilepsy, with the result that the various bromides, either singly or combined, have so far given the best results in relieving this distressing disease. Dr. Charles S. Potts has sought some drug which would be equally efficacious in lessening the number of epileptic seizures and at the same time not cause the disagreeable symptoms which may follow the persistent use of the bromides. With this end in view, various drugs, as antipyrine, antifebrin, and bromide of ammonium were separately tried, but with indifferent results until Dr. H. C. Wood suggested the use of antipyrine and bromide of ammonium in combination. Since then this mixture has been used with excellent results in the treatment of forty-three cases of idiopathic epilepsy. In none did it fail to cause marked amelioration of the symptoms, and in some it gave relief when all the other commonly-used remedies had failed, and in none has there been any indication of bromism, or of the disagreeable symptoms to which antipyrine sometimes gives rise.

For adults the dose, which is given three times a day, contains six grains of antipyrine and twenty grains of bromide of ammonium.

TREATMENT OF INGROWN NAIL.<sup>8</sup>

Dr. Pürckhauer moistens the surface of the diseased nail with a lukewarm forty-per-cent. solution of caustic potash, and then scrapes off the softened upper layers with a sharp-edged piece of glass. After a second application of the potash solution the scraping is continued until the nail is as thin as a sheet of paper. It is then lifted up from the soft parts with forceps and the diseased parts are excised.

PREPARATION OF SACCHARIN.<sup>9</sup>

R Saccharin,	. . . . .	150 grs.
Bicarbonate of soda,	. . . . .	75 grs.
Distilled water,	. . . . .	Oil.

One part of this solution is equivalent to two and one-half times as much sugar.

CHLOROFORM AND PHTHISIS.<sup>10</sup>

Dr. Samuel O. Potter reports that he has discovered a cure for tuberculosis in the almost continuous inhalation of chloroform. As a result of some experiments he feels convinced that this bacillus may be destroyed, and its victims saved, by the continuous use of chloroform inhalation systematically carried on, day by day.

by means of suitable apparatus, and with the care necessary to prevent injurious results or accidental poisoning. It is not necessary to induce anæsthetic action, but the inhalation can be kept up continuously for several hours daily, and maintained short of general anæsthesia.

(To be continued.)

## New Instruments.

TWO NEW VAGINAL SPECULA.<sup>1</sup>

BY WM. O. STILLMAN, A.M., M.D., ALBANY, N. Y.

In the use of the bivalve specula commonly employed in minor gynecological office work by the majority of physicians, several mechanical defects have annoyed me. The principal one of these has been that, in the case of virgins or women with small vaginal openings, it is often difficult to expand the speculum enough to freely discover the os externum without causing undue pain or perhaps lacerating the hymen. In other words, in order to expand the wings of the speculum sufficiently for practical purposes, it is necessary to dilate the ocular end of the instrument more than is really necessary to see well, or secure room for such instruments as are ordinarily used in office work, as the uterine probe, curette, forceps, applicator, caustic, etc. It has seemed to me that the vulvar part of the speculum might be made of a moderate, fixed size, and the blades be made to expand independently, or, at least, without affecting the selected calibre of the more external part. To do this I spent odd intervals during a couple of years, devising machinery, but it was either too complicated or defective mechanically. Finally, it occurred to me that by simply carrying the joint working the blades an inch further in, I could very readily accomplish my object. A double end was gained in this way with the simplest possible mechanism. Not only does the vulvar portion of the speculum not enlarge when opened, but a retracting motion is given to the upper blade as it opens, by its shorter radius, which seems to me a very important desideratum in constructing a bivalve speculum to be theoretically and practically a perfect instrument. This motion much more readily exposes the mouth of the womb.

It seems as if many of the designers of vaginal specula have labored under the delusion that the uterus is placed at the end and directly in the axis of a short, straight tube, fixed at right angles to the vulva. Their instruments, and they are common, open like a pair of dividers. The joint is directly in the line of juncture of the two blades and the upper blade is as long as the lower one, and usually pushes the uterus up out of sight behind it when it is opened. They ignore the fact that the womb is placed at about a right angle to the plane of the superior strait, while the vulva is nearly in the plane of the ischio-pubic rami, two planes separated by a very wide angle. Sections of the frozen cadaver, and clinical experience have shown that the vagina is practically the segment of an arc, extending between the two planes just mentioned, and that the womb is frequently found at nearly right angles to the inner extremity of this arc, the pos-

<sup>10</sup> New York Medical Record, November 1, 1890.

<sup>1</sup> A paper read before the Albany County Medical Society, April 29, 1891.

terior wall of the vagina being longer than the anterior. As a concession to these anatomical facts many specula are now being made with the upper blade shorter than the lower one, a very desirable feature. But the retracting motion is very rare, although it works extremely well, usually, when found. This motion is well shown in an English speculum, purchased in London, which has been a favorite of mine. The joint is peculiarly placed as you will see, but the vaginal orifice is excessively expanded when it is opened widely.

Some specula found in the market are too narrow, and some too heavy; some are too big and clumsy, and some of the trivalves hurt or allow the vaginal vault to drop too low. Without devoting more time to what seem to me defects in other instruments, I will briefly summarize the practical improvements which I have endeavored to combine in these specula. In presenting the two, I will speak of the regular bivalve speculum first, and of the tubular bivalve later.

(1) I have sought to make it as simple as possible in its construction, and to render it aseptic it is made to come apart with the greatest ease.

(2) The vulvar part of the speculum is of a convenient size and does not enlarge on opening the speculum to its widest extent. On the contrary it becomes slightly smaller when fully expanded.

(3) The upper blade is shorter than the lower one, and working on a short radius retracts (so to speak) and exposes the womb very readily.

(4) The blades are broader at the free ends, so that a slight dilatation expands the vagina quite fully and prevents the folds of the canal from falling in at the sides and obstructing the view, as has been the case with me with one very slender speculum of a popular pattern. The breadth has been compensated for by excessive flatness when shut, to facilitate introduction, and the considerable height of the vulvar end is, on the other hand, compensated for by narrowing the instrument at that point, so that the calibre is not increased and yet a good view is obtained.

(5) It has been made light in weight, so as not to inconvenience by tilting or by pressing down on a sensitive hymen. Lightness is still further attained by the use of aluminum (one-third the weight of iron), which is, of course, non-corrosive (except to hydrochloric acid) and gives a pure white light by reflection, showing the correct colors of the parts revealed.

(6) To save tedious screwing and unscrewing in use, the set screw can be thrown in and out of its bearings, which also facilitates taking the instrument apart.

(7) An attempt has been made to adapt the shape of the instrument to the natural anatomic curve of the vagina, and it has been made quite wedge-shaped to assist in introduction.

I must acknowledge much courtesy and patience on

the part of Messrs. George Tiemann & Co., the manufacturers of the specula, from whom they can be procured, in carrying out my ideas, which they have done very perfectly. For the best results this speculum should be made in sets of three sizes, the one shown representing the medium size.

The second speculum, which is simply an improvement on the well-known tubular ones — making it more easy of introduction, self-retaining, and giving a greater range of vision than usual — has many of the advantages of the first one, but is not aseptic. It works extremely well in practice, however.

Both of these specula have answered my requirements very well, and I can simply say in offering them for your inspection, that I have given them a trial of many months' duration, and that I do not think that they have the defects of which I complained, and from which perhaps some of those present have experienced annoyance.

I know it is much the fashion among specialists and many physicians, to rely almost wholly on the Sims speculum. The lack of office assistance makes this impracticable for the mass of physicians. Although I am never without an office assistant, I have found the bivalve speculum quicker, less liable to alter the normal relation of the parts, and in the majority of cases more satisfactory than the Sims, which is, of course, unequalled for many purposes.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. THE ONE HUNDRED AND TENTH ANNUAL MEETING.

BOSTON, JUNE 9 AND 10, 1891.

#### SECTION IN SURGERY.

(Continued from No. 3, page 66.)

DR. ALFRED WORCESTER, of Waltham, said: Mr. Chairman and gentlemen, I believe the only advantage which I have over the other gentlemen present is that I have been through it myself. I have been very much gratified by what I have heard, and I certainly notice a great difference each year as to the treatment recommended by our first surgeons, and I am as certain in my own mind that we will have to wait but a few years before the right treatment will be laid down and applied, and that is to operate first, last and every time in the cases of appendicitis. When that was first broached, the necessity of operating in every case, it was laughed at by very nearly everybody, and now it is laid down for us that we should certainly operate in those cases which are going badly, perhaps, not in those that are going to recover, anyway; but, it is at the same time told us, that there is no possible way by which we can tell what cases are going to the bad. Now, whatever the percentage of cases treated medi-

cally, it certainly is not a large one; there certainly is a large per cent. that will not recover unless receiving surgical treatment; and of the class of cases that will recover only if surgical treatment is given, a very large proportion will recover only if that treatment is given early.

All the dangers of the operation, all the difficulties, all the dangers resulting afterward, do not apply if the operation is done at the outset of the disease. It is a very difficult thing indeed, every one admits, to save a case by operation where there is an indistinct abscess cavity and perhaps a general purulent peritonitis. You have heard it laid down this afternoon that, in general acute peritonitis there is no such thing as recovery. I am sure that I have seen such a case recover, where the abdomen was thoroughly washed out, where the appendix was in the pelvis, was found and was taken out, the stump was properly treated, and the patient recovered. But in cases at the outset, before the appendix is perforated, whether gangrenous or not, there is no such thing as disaster.

It is a simple operation, it is easy to find the appendix, there are no adhesions in the way, it is easily removed, the stump can be properly treated, and while I say that, I want to say that I do not believe it proper treatment to ligate it. It seems to me that that is unsurgical; it is not like ligating the Fallopian tube, it is like ligating a part of the bowel, and when the part separates, what is to hinder an escape of fæces? Of course, there may be resulting inflammation that will close it, but the proper way, it seems to me, is the treatment applicable to any other opening into the bowel, bringing the surfaces together. It is not easy to pull in the edges, but if the core of it is dug out by a V-shaped incision, the edges can be turned in easily. But this proper treatment of the stump can only be done when the operation is done early; it is not possible when you find the appendix ready to drop off as you touch it — it is not easy then to repair it properly. It seems to me that the reason why so many cases have proven fatal is, that the result has been lost sight of, that the bowel is really perforated. And what sense is there in leaving out of consideration the question of the integrity of the bowel? If the operation is done in the last stages of the disease, after three or four days, the sloughing appendix is fished out, and we depend on a rubber tube, let down into the abscess, near the stump, that is not any more sufficient than if we depended upon a drainage in the abdominal cavity by a tube running down somewhere near a perforation in the bowel. It is recognized, it seems to me, in every other variety of bowel wound, that it is necessary absolutely to close any perforations of the bowel before the abdominal walls are closed up. It seems to me that it is just as necessary here.

It seems to me that the main difference arises from the fact that appendicitis is claimed to be within the physician's province until a certain time, and that it is for him to decide when to call in the surgeon, and the surgeon comes and is relieved of the responsibility of the case; he is called either too early or too late. If you get him out too soon it is "too soon." If the patient dies it is "too late." Gentlemen, appendicitis must be treated by the surgeon from the first to the last; it is just as much a surgical disease, and entirely within his province, as any disease that can be thought of. There is no use in leaving the physician to decide when to call the surgeon in, for he will not call him in

until he finds that he cannot save the patient himself. Sometimes the end of the first day is later than the end of the first week in other cases. It will not do to shift the responsibility upon the man who will be called the next day.

I want to point out one great advantage in the early operation, and that is that it is easier to diagnose the disease in the first twenty-four hours than at any subsequent time. All the symptoms are more apparent at first. After the belly is swollen out no man can diagnose the case, except by abdominal section; but, at first, when the abdomen is flat, when you can, by deep pressure, get all over the abdominal cavity, it is generally easy to decide whether it is a case of appendicitis or some simulating attack. And then the ease of operating, that is the thing that I want to impress. I would rather have appendicitis under the care of a country surgeon in the very end of the state, who was willing to operate the moment he recognized the disease, than to be under any of the surgeons who would not operate, although they recognized the disease early, because it is impossible to tell what cases are going to the bad. In the very worst cases of appendicitis, the patient in that condition will have a good pulse and temperature. Beginning collapse is not very easy to recognize. I have seen cases where you could hardly persuade the patient himself that he was very sick, where death was already stamped upon his face. So I say I would rather have the care of an experienced surgeon than to run my chances under a man who felt that by waiting he could tell the best time for operating. What does that mean? It is an easy operation, I am willing to admit, when the inflammation resulting from the perforating appendix is well walled off. But just think what slippery bricks that wall is made of. It is nothing more than coils of intestines. A cathartic will break that down. A little increased peristalsis will break the wall, and the pus is diffused. In some cases, of course, it is an easy operation to evacuate the pus, but after the pus is out fæces generally follow. That means that the integrity of the bowels is lost; it means that there will be recurrence, that there will be sloughing of the edges of the wound. If it is taken early it is just as clean an operation as if done between the attacks. It is easier if done in the first attack. There is great difficulty in the intervals between the attacks. There are adhesions everywhere. The appendix has sometimes not been found, and even if it is found it is quite a serious operation, for the adhesions have to be broken down; but in the very first attack there are no adhesions in the way, you can easily find the organ, you can treat the stump, you can close the wound without putting in a drainage-tube, and you can have the man at work in a few weeks' time, as I have had the pleasure of seeing.

We are asked how it is we have so many cases in Waltham. Perhaps it is that we do not have to sign our death certificates as peritonitis. We report our cases. Now, if any of us have operated so far in a case where there was no appendicitis, or where any injury resulted from the operation, then I admit we stand properly impeached. We have reported our cases, except our last dozen, for the last year, and they will be reported very soon. And when that is a record of cases operated on in the first twenty-four hours, and when we found that in some of them the appendix was gangrenous from the outset, and when

we report that out-patients are at work after a very short and sure convalescence, I think we have the right to hope that the time is not too far distant when what I said at the beginning will be held true, that the treatment of appendicitis belongs to the surgeon from the first; and in the great majority of cases the patient's chances will be better if he is operated on as soon as the diagnosis is made, and that being so, the duty rests upon every one of us to operate just as soon as the diagnosis is made.

Dr. J. W. ELLIOT said: If any of you have any doubt that perforating appendicitis is like a bullet-wound in the intestines, you may be interested to see these appendices which I have excised within the last year: That appendix was sloughing out at the end of the fourth day. That had an opening in it very much like a bullet-wound; on the third day that patient had a purulent peritonitis. Here is another case, operated on the third day, with a sloughing, gangrenous appendix, which was wrapped up in the omentum, illustrating that phase of the disease. Here I pass around a case of chronic appendicitis. I will not report any of these cases, as they have all been reported.

Dr. Worcester certainly made a very strong plea for early operations, and I very nearly agree with him, but not quite. It seems to me it is the dread. We are all afraid of appendicitis when it begins. We do not know what will happen. We know that the cases are very dreadful. I think it is your instinct to operate immediately on every case, to avoid any disaster; but I am sure that the facts will not sustain that position. The third part of Dr. Fitz's cases recovered without operation. That is a very large number to be thrown out of consideration.

Last year I was called in consultation in private practice, in thirteen cases. Six of them were operated on; seven were not operated on; and all the seven recovered perfectly. All of those cases had serious symptoms. If a patient has a purulent gonorrhoeal endometritis, there is great danger of salpingitis, perforation and death; but surely, that is not a reason for operating and removing the tubes. This is not intended to be a fair parallel, but it illustrates a point which I want to bring out later. What we want to do is to find out when we shall operate, and when we shall not, and what we shall do when we operate. I except all chronic cases, all old cases that are walled off; these will not come into consideration with me to-day. The question is, When shall we operate? As I said, one-third of the cases, according to Dr. Fitz, recover without operation. I have seen very severe forms of appendicitis, and am very much afraid of it; but there are certain mild cases which I see, which I feel confident from the start are not going to require operation, and usually do not. But if you make that general statement, some one who does not know what the symptoms are which should cause alarm will surely go wrong. Constitutional symptoms should be relied on. It is the cases with temperature under 100° and pulse under 100 which die for want of the operation. Now, I do not pretend to solve this problem, but there is one thing which I think helps me a great deal, and I think may help other people; and that is, it seems to me the difference between the old and the new surgery. In a very general way this difference is that the old surgery depends upon the general symptoms, the new upon what you find locally. It is skill in examining which has made great advance in the treat-

ment of salpingitis, and operating as soon as we know that the dangerous local condition is present, before constitutional symptoms appear, that has made the difference.

Thus I hold that all symptoms which indicate that a local process has begun in the region of the appendix are to be very seriously considered, and almost always are a sufficient reason for operation. I should always operate in the presence of a tumor; I should always operate in the presence of general distention and tympanites; I should always operate in the presence of continued pain. Of course, when the constitutional symptoms are violent, they are often in combination with local symptoms. And violent constitutional symptoms should certainly be acted on. Yet constitutional symptoms, in my experience, are not so valuable as local symptoms.

I have had a case within a year where there was elevation of temperature, with only moderate local pain, with no distention. There was no question about the diagnosis. The temperature gradually fell to normal, there were never any symptoms of thickening, and the patient made a good recovery. On the other hand, I have had a patient with pulse and temperature practically normal on the third day, the abdomen rigid, expression that of a very sick person, where on operation a purulent peritonitis was found. Now Dr. Worcester wishes to lay it down as a general rule that it is better always to operate, but from the scientific point of view, that thirty per cent. must be taken into consideration, and what we want to do is to work out the symptoms, to get at the exact value of all the symptoms; and I am perfectly sure, that I can do a great deal more now, after experience in reading the symptoms, than I could three or four years ago. I should say then, not to operate on every case as soon as the diagnosis is made, but operate on every case as soon as any symptoms appear which are really threatening, and that from the point of view of one who has weighed carefully the value of symptoms.

Dr. F. C. SUATTUCK said: I should like to protest somewhat, from the point of view of the physician, against the position that appendicitis is to be operated upon as soon as the diagnosis is made. Perhaps my experience has been unusually fortunate. It certainly has not been very large; but I have collected the cases which came under my care in the wards of the hospital in the last two or three years, fifteen in number—cases in which the diagnosis was clear. In these cases, most of them, consultations with my colleagues were held, so that the question of operation was not dismissed without consideration. In only four of these cases was operation done. These four all recovered. The other eleven that were not operated upon all recovered. It seems to me that we can divide the cases roughly into three categories. One class demands operation. In the second class there is no question of operation. In the third class are the doubtful cases. That doubt is a very serious one. These are the cases which arouse the greatest anxiety in the attendant. It seems to me that we must go wrong occasionally in these cases. Whether the contingent of accidents will be any larger from failure to operate where operation ought to be done, than from the results of the operation itself, where operation was not necessary, I do not know. Even in these days it is a serious thing to open the abdomen, and it seems to us that the surgeons who

have had the largest experience are those who are least willing to operate unless they are very certain that it is desirable.

Let me instance one or two cases which come under this class. One was a gentleman whom I saw within a few hours of the attack. He went into the hospital. I asked Dr. Cabot to see him with me. He had a tumor, well pronounced, and was pretty sick. On the ninth day, I think, Dr. Cabot made the remark, that if he were in the wards he would be operated upon. It was decided to wait a little, and the next day he was a trifle better, and he got entirely well without an operation. The tumor disappeared entirely, and he had had no trouble of any kind. That is one case. If the man had been in the ward he would have been operated upon. He was not, and he got entirely well.

A second case, which Dr. Warren and I had together. The patient entered on the medical side on the fourth day of the disease. On the tenth day she was transferred to the surgical side. Dr. Warren saw her almost daily before the transfer. She got rather better, and I think she was re-transferred a day or two later, only to be transferred once more. The operation was on the fifteenth day. She ought to have been operated on earlier. She got well.

Then, one private case, which I saw for the first time on the fifth day, — a boy of fifteen. The pulse was over 120; the temperature a little over 100°, vomiting; very ill. I asked for a surgical consultant immediately. After careful consideration it was decided not to operate that day, to wait until the next day. The boy seemed so sick that it did not seem that he could come out of it. On the next day he was better, and apparently became convalescent. I did not see him again until the tenth day. On the eleventh day I saw him, and he was operated on a few hours afterward. He had an enormous abscess in the side, and died a few hours after the operation. Yet there was a very careful consideration on the fifth day by a most competent surgeon. Some mistakes will be made inevitably. It seems to me that there is a pretty large proportion of cases that get well without operation; and I certainly am not prepared to say that the knife should follow immediately the diagnosis of appendicitis without the consideration of anything else.

DR. S. H. WEEKS, of Portland, Me., said: I consider myself very fortunate in hearing this discussion on this subject, in which I have had so much interest, by men of eminence and large experience. I must confess that it is apparent to me now that even here the full sunlight does not shine upon this important subject; we are not prepared to say that this method or that method is the best. I am satisfied that the early operation is not the best operation. Inasmuch as it is true, as you have heard here to-day, that a large number of patients with appendicitis recover without surgical operation, and inasmuch as we cannot at first decide what cases are to recover, we must wait until we are satisfied that this particular case demands the surgeon's knife. Furthermore, I believe that in the cases that require operation later on there is an advantage in waiting. There is an immense advantage in having a peritonitis which is circumscribed when the surgeon operates; and my first endeavor is to limit the inflammation, circumscribe the suppuration, and if I can secure that, if I can secure circumscribed perito-

nititis and circumscribed abscess, then, if I come to operation, my patient will very surely get well.

Now there are two different plans in the early stages. I do believe in the saline cathartics in the very beginning. I know from my own experience that thorough action of the saline cathartics, unloading the canal, relieving the bowels of the accumulation of gas and fecal matter, does bring a tendency to circumscribe the inflammation, to limit the suppuration; and I also believe in the early application of leeches and then fomentations. It seems to me that this plan of treatment in the main is the best plan, and a plan which is applicable to all cases, — those cases that ultimately get well without an operation, and those cases that require the surgeon's knife later on. In the course of three or four days we are able to say what cases will get well, because those cases that get well without an operation at the end of three or four days begin to show signs of convalescence, and recovery gradually goes on. If at the end of that time the symptoms are no better, if there is a remission, then that is the time for the surgeon to step in.

One word with reference to the remark made by Dr. Worcester as to the opening in the appendix being the same as an opening in the intestines; it is not true. I am sure it is not true. What is the function of the appendix? It is simply a lubricator. It has no secretion. It is not a part of the intestinal canal as to its function. Fecal matter does not circulate through the appendix, and when a foreign body is found there, it is not a grape seed or something which has found its way there; it is a concretion which has formed there, just as a biliary calculus is formed.

Now, with reference to the ligation of the appendix at the time of the operation, I pay but very little attention to it when I operate. I simply open the pus cavity, wash it out, and leave the appendix untouched, unless it happens to lie in the cavity where I can reach it. In no case has there been a fecal fistula. This is the point: I think the opening into the appendix is very different from the opening into the intestine.

DR. S. C. GORDON, of Portland, said: For the last two years I have had some convictions about the matter under discussion. That is a good deal to have in a matter of this kind. My convictions have amounted to substantially this: that we have been paying altogether too much attention to the appendix, that we are called to a condition, and that condition is one of peritonitis. Now for practical purposes I do not care what the cause of that peritonitis is, I am going to treat that peritonitis exactly as if I do not know what the cause was. My treatment has been purely the saline cathartics from the start. Suppose you remove that cause, you have not removed the condition. I think there is the mistake of the surgeon. "Only let us get at the cause." Medicine has been saying for thousands of years, "Remove the cause, and you have cured the disease." It is not true, it is all false; and surgery has done an immense deal of harm on this idea. An appendix producing appendicitis is no worse than a great many other things producing peritonitis. I do not care whether an appendix is the cause of the peritonitis. It is peritonitis that I am called for, and that I am going to treat by the modern approved method of treating peritonitis. The only wonder is that we did not do it fifty years ago. We did fifty years ago; but thirty years ago we began to be wiser, and Alonzo Clark ruled the medical and surgical

world. It is only such a man as Tait who had the courage to come out and say cathartics are the thing to treat peritonitis with. Therefore, I believe that if we will stick to the idea that we are called to treat a condition, we are going to save nine-tenths of the cases of appendicitis without operating.

No amount of medical or surgical treatment will save all patients. But if you are going to get a localized abscess, you are going to get an abscess with the walls of very much more integrity if you treat it by saline cathartics, if you unload the vessels; for you then have an abscess wall which has some vitality to it. If you have allowed that patient to go along without relieving the condition, if you have everything in the intestinal canal, your vessels are crowded and the tissues they supply die; but if you have unloaded the vessels and relieved all this congested and inflamed condition that you can, you are going to preserve the integrity of the exudate. When you have your abscess well defined, you need not hesitate; take your time to satisfy yourself that you have a localized abscess; take your time, and open it; take out your appendix, if you can; if you cannot, let it alone; drain the abscess; and I believe you are going to cure the cases that can be cured by operative surgery. This is my belief, this is my plan, this is my conviction. I think we have paid altogether too much attention to this appendix. It does no more harm than anything else. Therefore, I think it is the medical man who is going to treat peritonitis successfully, for he is going to use modern methods.

DR. H. O. MARCY, of Boston, said: I had little idea, sir, of saying anything. I think, in common with most of you, we have been very much interested in this subject in the last three or four years. One of the first subjects that I ever studied in medicine was the letter published under the title of "Another Letter to a Young Physician," written by Dr. Jackson. There we find clearly and carefully laid down many of the very factors which we are now discussing. I am reminded, however, by my friend, Dr. Gordon, of the discussions which occurred about fifty years ago in London, between Sir Benjamin Brodie and our famous Dr. Watson. Sir Benjamin asked Dr. Watson if he would have the kindness to give his opinion, and he said: "It is good surgery, sir, that we might remove the causes, and thus their effects may be taken care of."

I am also reminded of a discussion in Washington, a few days ago, when, after the surgeons had said a good many things, one of the company arose and said he wanted to tell his experience. He had a case of appendicitis recently, and he was in doubt, so he asked in a fellow-surgeon. He thought it wise to operate at once and within an hour the buggies of the three surgeons were at the door. Then a brother came upon the scene and refused to allow the operation until it should be determined that his sister was going to be sick. On the second day she was out.

I am delighted to find that my friends, Dr. Weeks and Dr. Gordon, take practical medical views, and yet it seems that we may discuss it a little more at length, for it really, after all, is not the ordinary condition that we call peritonitis. We have a local septicæmia, a local septic condition, which is going on first in that little organ, and it is owing to the result as to whether it shall remain or whether it shall become constitutional, that your patient recovers or dies.

I am sure, as I look over my history of twenty

years or more of surgical watchfulness, I have seen such patients go to their deaths and the autopsy show that that patient ought to have recovered. My friend Dr. Worcester has pointed out that this is the fact. Within the last five years I have operated eight times and seven have recovered, and I cannot help thinking, had I not operated, that the result would have been far different. Formerly we saw these patients going to their death, and thought that we were doing all we ought to. Now let us see what takes place under modern surgery. We are able to tell you that at least nineteen cases out of twenty will recover if you take them in the condition where you can remove the appendix. If that is true, it is wiser practice, because the danger is less. Otherwise you are waiting for nature to do what she sometimes utterly fails to do, namely, to circumscribe the abscess. Our fathers knew how that should be cared for. Unfortunately there comes the time when the circumscription of the inflammation ceases, and where the first case I operated on showed clearly that I had waited forty-eight hours too long.

It is in just this class of cases, and in this only, that we want special light, and it is here our knowledge utterly fails, for we cannot tell when our inflammation is going to leave and where our danger lies. I should say, if I wanted to give my opinion in a word: If there is any doubt, give the patient the benefit of it, and operate. I have watched cases carefully and not operated; but there come cases where it is clearly your duty not to wait any longer, but to give the patient the benefit of modern surgery, and then we shall save a much larger percentage of our cases than we can do by saline cathartics or by waiting to see if nature herself is competent to do it.

DR. J. C. IRISH, of Lowell, said: I do not feel that I can add very much to this discussion. In all these appendices that have been presented here we can see that more or less tissue is necrotic. I do not see how it is possible for nature to care for those cases.

DR. G. W. GAY said: The brief remarks which I have to offer upon this subject are the results of experience. I do not wish to be dogmatic in my remarks, for there is yet much to be learned in this and allied affections. Experience tends to show that the majority of cases of non-traumatic peritonitis in the male are due to inflammation of the appendix. In the female, salpingitis, pelvic cellulitis, and kindred affections are to be considered in the etiology. Many cases of so-called "obstruction of the bowels," with peritonitis, have their origin in the appendix, and when seen late, should be treated as appendicitis, even if there be no localization of the symptoms. General peritonitis often begins as a local affection. The characteristic early symptoms may have been obscure, overlooked, or very likely have become masked by others before coming under the attention of a physician.

Localization of symptoms at any stage of the disease is of great importance as an indication of the character of the disease. The earlier these patients are seen, and the more closely they are watched, the more certain will be the diagnosis and the more intelligent will be the treatment. Pain in the belly, increased by coughing; tenderness, greater in the right lower quarter; and rigid abdominal muscles, more marked upon the right side, are among the most constant early symptoms of appendicitis. If the affection is located deep in the true pelvis, the rectal examination rather

than the vaginal will probably reveal its existence. Chills, fever, constipation of gas as well as of feces, and prostration, all go to confirm the diagnosis of appendicitis or other serious lesions in the vicinity.

The symptoms of a true convalescence are easily recognized; but in many instances it is by no means easy to form a correct opinion of the patient's real condition, before that stage is reached.

Mild cases will often recover in a few weeks under the "expectant" treatment; that is, rest in bed, opiates, leeches, poultices or fomentations, and a judicious diet. Occasionally a case is met with in which the symptoms are threatening at first, but soon reach their climax, say in two or three days, and rapidly disappear, leaving the patient with only an occasional twinge to remind him of his trouble.

Operative measures are indicated under the following circumstances: Severe cases should be operated on in from two to five days, according to the urgency of the symptoms. If they are seen to grow worse every six to twelve hours, radical measures should be resorted to on the second or third day. Collapse generally means perforation of the appendix, and calls for immediate operation unless the patient's condition forbids it. Cases in which the symptoms are not very severe, but are steadily growing worse, had better be cut in about eight or ten days. Cases in which the symptoms are mild and stationary, not progressing in either direction, call for an operation in from two to four weeks. A recurrent attack not infrequently requires operation; and the more severe the previous illness, the earlier should radical measures be resorted to.

Chronic inflammation (catarrhal) of the appendix may not suppurate. Nevertheless, the symptoms may be very distressing and persistent, forcing the patient to lead the life of an invalid. The peculiar feature of these cases is that relapses are of frequent occurrence as a result of over-exertion or slight exposure. An operation for the removal of the appendix, similar to Tait's for the removal of an inflamed Fallopian tube and ovary, promises the most certain and permanent relief under these circumstances.

Cases of severe general peritonitis which have never been localized, as a rule, are unfavorable for operation. It is difficult, if not impossible, to thoroughly wash and drain the peritoneal cavity by reason of the numerous adhesions which form in a few hours. Under these circumstances, an operation probably has little, if any, effect upon the course and result of the affection. The surgeon, however, is not infrequently led to operate upon these cases from being called late to the patient, and from having insufficient knowledge of the earlier symptoms of the case to enable him to be reasonably sure of the character, and from the fact that the patients do recover under alarming conditions. And furthermore no other treatment offers any encouragement.

There is comparatively little danger in operating too early in the bad cases. There is far more danger in delay. Brief periods of improvement are oftentimes treacherous in these affections. In doubtful cases delay is justifiable, more especially if the patient is so situated that he can receive efficient aid at short notice. It is a question whether operators with the largest experience in the affections have not been more disappointed in the result of the expectant treatment than in the operation. Convalescence in the former

is not infrequently long and tedious, and the recovery not satisfactory. Relapse and recurrence are also not infrequent under these circumstances.

The presence of a tumor or other localized symptoms is by no means essential to an operation. If the affection is located at the bottom of the iliac fossa, or deep in the pelvis alongside the rectum, no tumor need be expected to present to external manipulation until the collection of pus is very extensive.

Other things being equal, patients probably do better and make a more satisfactory recovery if the appendix, fecal concretions, and other offending substances are removed at the time of the operation. A pretty thorough effort to this end should therefore be made in a majority of cases. Abscesses will not heal soundly while foreign bodies, — be they feces, a gangrenous appendix, or not, — remain inside.

Little danger need be apprehended from pus in the peritoneal cavity, provided a free outlet be furnished. Not infrequently those abscesses have to be drained through a healthy peritoneum, and these cases do as well as any. In my efforts to find and remove the appendix, I have in several instances broken through the limiting wall of the abscess, and have thus far seen only an occasional local tenderness, which has always subsided in a few days. A peritoneum that has once protected itself under these circumstances can be trusted to do it again. If it will tolerate the product of inflammation, it will surely tolerate clean fingers and instruments, which are much less irritating.

In conclusion, I would say, the greater experience serves to strengthen my opinion, that, unless the surgeon has great grounds to suppose that the appendix is not at fault, he is justified in exploring that region by operation in every case of peritonitis which is in a dangerous state and is growing worse, and also those cases which do not show signs of recovery in a reasonable time, under other methods of treatment.

DR. WM. F. WHITNEY then made some remarks on the position of the appendix, its minute structure, and its pathology, illustrating the subject by lantern-slides made from photographs taken at the Harvard Medical School.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, June 4, 1894, the President, A. L. LOOMIS, M.D., in the chair.

DR. RICHARD VAN SANTVOORD read a paper on  
THE PATHOLOGY OF THE ECLAMPSIA AND ALBUMINURIA OF PREGNANCY.

In it he reviewed the various theories on the subject which have been proposed by different writers, and expressed his own conviction that the trouble was probably due to some form of toxæmia. In support of this view he related, in detail, a case of which he had made a very careful study. During two pregnancies the patient was threatened with trouble, but only once did this amount to actual eclampsia. About two months before her second confinement she was attacked with clonic convulsions attended with frothing at the mouth, but they were of very brief duration, and she passed through this labor, as she had her first, without any convulsive seizure whatever. The kidneys were evidently but very slightly affected, as the quantity of albumen in the urine was small and there were never any casts, while the organs readily responded to diu-

retics. The specific gravity, however, was lower than normal, and the quantity of urea was small; though after each of her pregnancies the urine became normal in character. In this case there seemed to be a sub-acute cystitis. The lesson that such a case taught, he thought, was that in our apprehension of eclamptic trouble in pregnant women, we should not be guided too much by the presence of albumen in large or small quantities, but should watch carefully the quantity of urea in the urine and be on the lookout for symptoms of nervous disturbance.

Dr. H. C. Coe thought that cases of puerperal eclampsia were probably due to various causes, and that no one theory would satisfactorily explain them all. His attention had been particularly directed to the importance of pyelitis in this connection, and he had seen two fatal cases where this condition was found. He also spoke of the proneness of women of marked nervous temperament to eclampsia, and referred to the well-known fact that young unmarried women in maternity hospitals who suffered from great apprehension and mental depression on account of their condition were peculiarly liable to this trouble. Any serious diminution in the quantity of urine passed by a pregnant woman was always to be regarded as a sign of danger, and the house-staff in the maternity he attended were instructed to be constantly on the watch for such an occurrence in any of the patients awaiting confinement.

Dr. W. T. Lusk said that the theory of reflex irritation seemed on the whole the most satisfactory to him, and the more that he studied the subject the more convinced did he become that it offered a solution of some difficulties that other theories could not explain. Thus, in regard to the supposed connection between the kidneys and eclampsia, it had long since been pointed out that convulsions sometimes occurred in cases where there was no albuminuria or any trouble whatever with the kidneys, and, on the other hand, that many women with serious renal disease passed through pregnancy and parturition without any sign of eclampsia. The reflex theory was also very useful in practice, and he believed that whenever convulsions came on or appeared imminent, the indication was to empty the uterus as promptly as possible. The remedies usually recommended, such as chloroform, chloral, veratrum viride, etc., were of service in securing a respite during which this might be accomplished, but the danger was that if they were continued too long they would lose their effect, and the patient would succumb. After the uterus had been emptied the convulsions usually subsided without giving further trouble.

The President having referred to the importance of high arterial tension in eclampsia, Dr. VAN SANTVOORD said that the existence of such tension was generally recognized, and that the advocates of the toxic theory considered that it was due to the effect of the poison in the system, while those of the reflex theory believed it to be due to reflex irritation. As to the case which he had narrated in the paper, he did not think this could be satisfactorily explained by the latter theory.

A TEMPERANCE MEDICAL CONGRESS was held at Prohibition Park, Staten Island, July 15th and 16th, under the auspices of the American Medical Temperance Association.

## THE BOSTON

## Medical and Surgical Journal.

THURSDAY, JULY 23, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.*

*All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.*

*Remittances should be made by money-order, draft or registered letter, payable to*

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

## THE DISCUSSION ON ANÆSTHETICS AT GLASGOW.

The action of anæsthetics is a subject of constant interest. Perhaps no therapeutic phenomenon has been so constantly debated and written upon since the introduction of surgical anæsthesia. But some very notable additions to the literature of the subject have been recently made, and the discussion in the Medico-Chirurgical Society of Glasgow, which occupied three sessions of the Society, the report of which has been recently issued, deserves attention.

The object of such a discussion, in the words of Dr. Joseph Coats, is to keep men's minds alive to the dangers incident to the use of anæsthetics, and to see whether, by the mutual comparison of experiences, we may be able to assist each other in avoiding these dangers. The immediate cause of the Glasgow discussion was the occurrence of a fatal case, and a proposal to regulate by law the administration of anæsthetics.

The discussion was participated in by advocates of ether and chloroform, and by others whose preferences seemed to be divided; but, if we may judge by the concluding remarks of the president, Dr. Macewen, individual opinions as to the relative value of these two substances, remained unchanged at the close of the discussion. The advocates of chloroform had certainly the advantage in point of numbers, but the claims of ether were ably represented by Dr. Hartly of Leeds, among others.

The discussion was practically limited to the respective values of ether and chloroform, though something was said as to the value of nitrous oxide for minor operations of short duration, and methylene found at least one advocate. The statements as to the comparative value of ether and chloroform vapors, as given by the physiologists or those who looked at the subject from the physiological and experimental side, were decidedly in favor of ether, as failing to show the depressing action of chloroform upon the heart. Dr. Coats puts the matter in few words, after a somewhat lengthy paper on the physiological details, as follows :

"I am firmly convinced, from multiplied experiments, that ether exercises much less of a paralyzing action on the intrinsic ganglia of the heart than chloroform does. . . . I do not know what is their relative action on the respiratory centres, but I suspect that in this respect also ether has the advantage over chloroform. So far as laboratory experiments are concerned, I believe that ether comes out distinctly better than chloroform, but I freely acknowledge that the matter cannot be arbitrarily decided by laboratory experiments. . . . If the superior safety of ether during the immediate administration is more than counterbalanced by the more serious after-effects, or by its inconveniences and difficulties during prolonged operations, then the scale will turn in favor of chloroform."

The advocates of ether seemed to prefer, as a rule, the use of some form of apparatus for its administration, and one reason for opposing its use as stated by Sir George MacLeod, was the assumed fact that it required an apparatus.

Statistics, so far as quoted, showed a much greater number of fatal results from chloroform than from ether, but the value of statistics was doubted by the chloroformists. One reason for their scepticism was the belief that deaths from ether occurred some days after operation from respiratory troubles directly due to the etherization, an imputation which was generally denied by the ether advocates. One speaker, however, quoted Dr. Woods's Berlin address, with approval, to the effect that "the ratio of deaths from chloroform is probably at least four or five times that of deaths from ether."

Sir George MacLeod spoke from thirty-five years' experience in anæsthetics, as he could recall the birth of anæsthesia. He freely admitted that anæsthetics did to some extent put the life of the patient in danger. In every case there is an element of risk. An anæsthetic should not be administered unnecessarily; but if an operation is required, there is more danger from shock than from its proper use.

There was expressed a certain general dread of primary chloroform syncope, which term is used to designate the form of sudden death most common under chloroform. In the language of Dr. Kirk, "it is beyond dispute that the majority of deaths from this agent have taken place in the early stages of the inhalation and in a somewhat sudden manner."

A marked difference of opinion was expressed as to the value of the preliminary administration of alcohol or morphia. By some alcohol was regarded as enabling the feeble to take the anæsthetic more easily and with less depression, while others seemed to regard it as highly deleterious.

Sir George MacLeod believed that "danger arose in most cases from want of experience in interpreting those small indications of the approach of danger, which could be learned only by long and careful observation. However invidious the statement might seem to be, he did not hesitate to assert that very few knew how properly to administer anæsthetics."

It seemed to be a common opinion that special pains should be taken to educate medical students to a practical knowledge of anæsthetics, such as would be attained by their repeated use under the supervision of an instructor; and the granting a diploma or certificate of proficiency to students so instructed, was a favorite idea.

On the whole, if very diverse opinions may be put together, it seemed to be the opinion that there was danger in the use of chloroform. There was an ill-concealed tendency on the part of some who had used it habitually for years without accident, to consider that improper administration was a possible cause of accident; others admitted a greater danger inherent in the drug itself; and one speaker (Dr. Beatson) wished the Society to make the declaration, "as a moral support to every one of us in our daily work when we have to deal with the drug," that at times chloroform, no matter how carefully administered, acts insidiously, and may cause sudden death by cardiac syncope.

One of the chief advantages to be gained from such a discussion is a stimulation to renewed interest in the clinical details of anæsthetization and any one who studies the report of the Glasgow meeting will be a more trustworthy anæsthetist, whether his favorite remedy be ether or chloroform.

#### LANNELONGUE'S NEW METHOD OF TREATMENT OF TUBERCULOSIS.

At the meeting of the Academy of Medicine, Paris, France, session of July 7th, Professor Lannelongue described his method of treating tuberculosis, founded on the substitution for the tuberculous neoplasm, of a compact, fibrous tissue which destroys the morbid tissue.

Lannelongue found, by experiments on animals, that chloride of zinc injected into a part produces a remarkable fibroid transformation in the normal tissues. On repeating these experiments in animals rendered tuberculous, the solution being injected outside of and around the tuberculous foci, the same results were obtained, a violent inflammation ensuing, which occasionally ended in abscess, but generally in a new formation of sclerous tissue, and even in disaggregation and absorption of caseous masses. Similar experiments have, with therapeutic intent, been tried during the past year on the human subject, for tuberculosis of the joints, bones, glands and lungs. Twenty-two such cases are reported, and the results in many of them appear to be excellent. All of these patients were under fifteen; twenty had been affected with osteoarthritis of the limbs or vertebral column, or with tuberculous adenitis; two were victims of pulmonary tuberculosis, and bore the injections well. The latter cases are still under treatment, and no prognosis is yet ventured. In the twenty cases first mentioned, there is reported a manifest tendency to reparation. The benefits of the treatment were the most striking in

several patients formerly disabled and bedridden from fungous arthritis, who were able to be presented to this meeting. The joints had regained their normal form and functions, and walking could be performed with ease. Lannelongue thinks that if the bacillus still persists in the sclerosed tissues (a question not yet definitely decided), it is confined in a place where it is, as it were, encapsulated and inoffensive.

Lannelongue's method (called by him "sclerogenous method") is based on the principle of acting on the zone of tissues in propinquity to the tuberculous fungosities and neoplasms, that is, on the parts which contain the vessels which feed the tuberculous growth. It is easy, in most of the joints, to create nodular tissue, hard and compact, on the surface and in the fungosities. All that needs to be done, is to convey the chemical agent to the margin of the fungosities, and there deposit it, in the proper "dose," at the same time establishing a certain number of points of contact; the medicament diffuses itself considerably beyond the place of application.

He generally makes use of a ten per cent. solution of chloride of zinc, and deposits two or three drops at a determined point; the operation is repeated several times, either without removing the needle, its point being directed a little to one side, or by making several punctures. In operating about the knee-joint, for instance, with the view of substituting a fibrous for a fungous osteo-synovitis, an injection is made just above the upper cul-de-sac in such a manner as to deposit the solution upon the femur near the reflection of the fungous synovial membrane, and, if possible, under the periosteum. There are thus deposited deeply in four or five spots corresponding to as many punctures, about the circumference of the upper cul-de-sac, eight to ten drops of the solution. The injections at the sides of and below the ligamentum patellæ require more care; only about two drops should be injected and the needle should be made to penetrate the aponeurosis and engage in the superficial layer of the fungosities. A final injection is made parallel with the upper border of the epiphysis of the tibia; care should be taken not to penetrate the knee-joints, and it will not do to throw the injections immediately under the skin for fear of an eschar. When the injections are made deep, there is no danger of an eschar forming.

The one to ten solution is applicable to costal and iliac tuberculosis as well as to strumous adenitis. When the glands are the seat of caseous foci, the treatment provokes an irritation which leads to abscess.

Lannelongue thinks his treatment applicable to dry arthritis as well as to the fungous kind, and has tried it in one case of canceroid with immediate benefit; a relapse, however, soon took place.

At the same meeting, Leon Le Fort stated that as early as 1879 he had taught the possibility of modifying articular fungosities by means of interstitial or intra-articular injections of sulphate of zinc. He has noticed that around the focus of injection the fun-

gosities became more consistent and after a while diminish in volume; in some cases he has obtained a cure. One of his patients, treated for fungosities of the knee, whom he, in 1879, presented to the Surgical Society, was able to walk well in consequence of this treatment. For the past twelve years, he has from time to time had recourse to this practice, and he has noted marked improvement in cases of white swelling, especially when the treatment was begun early. Often, however, the cure proved to be more apparent than real, and after a time the disease resumed its course. He is in the habit of using a one to ten solution sulphate of zinc, and of injecting from ten to twenty drops. Has never had any untoward results. He prefers, however, to the interstitial injections of sulphate of zinc, electrolytic punctures.

Lannelongue, in closing, replied to M. Le Fort; (1) That he had never used sulphate of zinc, believing the chloride to be a much more efficient agent; (2) That he had never employed interstitial injections; (3) That he condemns intra-articular injections.

#### NEW YORK STATE EXAMINATIONS IN MEDICINE.

On July 11th, there was a conference at Albany of the three State Boards of Medical Examiners—Regular, Homœopathic and Eclectic—provided for by the new law enacted by the last Legislature. The object of the meeting was to discuss the details of the State examinations in medicine, which, after the 1st of September next, every new practitioner will be required to pass.

The chairman was empowered to appoint a Question Board of six members, to consist of two from each of the separate examining boards, for the purpose of preparing a syllabus in all departments of study except those of materia medica and therapeutics.

Four examinations were ordered to be held each year in the cities of Buffalo, Syracuse, Albany and New York, at times to be designated by the Board of Regents, after consultation with the faculties of the various medical institutions. It was also determined that examinations on all subjects should be held in the English language and at one time, and that all candidates must be graduates of medical colleges and have the degree of M.D. The conference then adjourned subject to the call of the chair.

Each of the three medical boards subsequently held separate meetings and arranged for permanent organization. The board of the Medical Society of the State of New York elected Dr. Wey, of Elmira, President, and Dr. Fowler, of Brooklyn, Secretary, and appointed them to represent the board on the Syllabus Committee.

#### MEDICAL NOTES.

A BUST OF HERRA was unveiled on June 14th in the arcade of the University in Vienna. An address was delivered by Professor Kaposi.

CHOLERA is prevailing with considerable intensity in Abyssinia. Quarantine is in force against arrivals from the Gulf of Alexandretta, in view of the cholera at Aleppo.

A WORTHY INSTITUTION. — An announcement appears in a Moutana paper that Dr. H. F. Musser has recently opened a hospital, where the unfortunate rich can find excellent treatment and comfortable quarters.

MEDICAL LAW IN NEBRASKA. — A law which goes into effect next month provides for a State board of Health, to consist of the governor, attorney-general and superintendent of public instruction, who shall appoint four secretaries, who shall be graduated physicians of at least seven years' practice. It is made unlawful for any person to practice medicine, surgery or obstetrics, or any of the branches thereof, in this State, without first having obtained and registered the certificate provided for by the act; and no person shall be entitled to the certificate provided for unless he shall be a graduate of a legally-chartered medical school or college in good standing; said qualifications to be determined by the board. The penalty for infringement of the law is a fine of not less than fifty nor more than three hundred dollars.

POPULATION AND ALTITUDE. — Census Bulletin No. 89 shows how the population of the United States is distributed in accordance with altitude. About a sixth of the people live less than 100 feet above the sea level, more than three-fourths are found below 1000 feet, while 99 per cent. have their homes on planes below the level of 5,000 feet. These various proportions are accounted for by the callings of the people, whether commercial, agricultural or manufacturing. An indication of the drift of the people is found in the fact that between the levels of 5,000 and 6,000 feet the population is much in excess of that on the levels between 3,000 and 5,000 feet. This is largely owing to the density of the comparatively new settlements at the eastern base of the Rocky Mountains and in the Salt Lake valleys. A review of the conditions in 1870 and 1880 shows that the relative movement of the population has been steadily upwards, and it has been in the course of the two periods that the regions above named have been developed. The average elevation of the country is about 2,500 feet. The average of altitude of population has been as follows: In 1870, 687 feet; in 1880, 739 feet; in 1890, 788 feet.

DECLINE OF INFLUENZA IN ENGLAND. — The Registrar-General's mortality returns for the week ending July 4th, satisfactorily demonstrate that the influenza epidemic is rapidly subsiding. The total death-rate for London fell to 16.8, from 19 in the preceding week and 23 for the week ending June 20th. The deaths primarily attributed to influenza, which six weeks before amounted to 319, were only 56; and there has been a similar decline in the mortality from respiratory diseases, the decline in the death-rate has

been tolerably general in all the large towns. Contrasted with that existing in the same places four weeks previously, in Birmingham it declined from 30.9 to 17.3; in Leicester, from 21.2 to 15.7; in Liverpool, from 31.4 to 20.2; in Manchester, from 29.1 to 23.1; and in Sheffield, from 22.9 to 17.5.

NOCTURNAL ENURESIS. — A correspondent of the *Lancet* advises for this trouble that the old-fashioned remedy of a birch-rod be employed shortly before the boy is put to bed, six not severe strokes repeated for two or three nights at the outside will effect a cure. The birching should be regarded by all parties not as punishment for the past, but as treatment for the future — a very different thing. The *rationale*, he thinks, is (1) that it wakes up a desire to avoid wetting the bed; (2) that it draws the blood to the surface for a few hours, and thus relieves the pelvic organs; (3) that it stimulates the lumbar centre, controlling micturition through the nerves distributed to the upper gluteal region; and (4) that it prevents the patient lying on his back.

CANCER INOCULATIONS. — It is reported by telegraph to the daily press that an excitement has been aroused in Berlin by the discovery that two eminent professors have been experimenting with inoculations of cancer on hospital patients without their knowledge or consent. They have selected such patients only as were past recovery. A similar scandal has recently been aroused in Paris. According to the *British Medical Journal*, the *Bulletin* of the Académie de Médecine, published on June 29th, contains the official report of a paper read by M. V. Cornil, at the meeting on June 23d. The facts of the case are, briefly, that *un chirurgien étranger*, who conceals his identity, took advantage of the insensibility of two patients, from each of whom he was removing a tumor of the breast, to graft a portion of each tumor into other, and apparently unaffected, parts of their bodies. He states that each of these grafts took effect; in one case the patient died, but not of the grafting; in the other case the patient was still living, at the time of the report four years ago, but she refused to undergo any further operation. This has been taken up by the daily press, apparently for sensational purposes.

#### BOSTON AND NEW ENGLAND.

NON-ADMISSION OF IMMIGRANTS. — Of the two hundred and thirty-two immigrants who recently came on the steamer *Michigan*, of the Warren line, twenty-eight were refused permission to land. These people are mostly Russian Jewish families, while a few of them are from Ireland and England.

THE FIRST BOSTON BOARD OF HEALTH. — The Board of Health has just had bound five volumes, the records of the board from 1799 to 1824. On the first page of the first volume is the call for the first meeting, which was called by members of the General Court, Hon. Thomas Daives and William Smith, who summoned representatives from all the wards in Boston. The meeting was held at Fanueil Hall on the 9th of March,

1799. Paul Revere was elected the first president, and John W. Folsom, secretary. A committee of three, consisting of Joseph Head, James Prince and Paul Revere, was elected on rules and regulations. The meeting then adjourned until the following Wednesday, when the house of Nathaniel Balch was the meeting place. The first two volumes were found in the City Hall about a year ago and the other three recently.

**DELEGATES TO THE CONGRESS OF HYGIENE.**—Governor Russell has designated as delegates from Massachusetts to the Seventh International Congress of Hygiene and Demography to be held in London, August 10th to 17th, Morrill Wyman, M.D., of Cambridge, and Samuel W. Abbot, M.D., of Boston.

**LYNN HOSPITAL ADDITION.**—A building to cost about \$10,000 is soon to be erected. The present plan is for a cottage two and a half stories high, to be used entirely as an administration building.

#### NEW YORK.

**BIRTH AND DEATH RATES.**—During the week ending July 11th, there were reported in the city 957 deaths, against 922 for the preceding week. This is a decrease, however, compared with the mortality of the corresponding week for the past five years, which averaged 1,239. The death-rate was 29.68 per 1,000 of the population, as against 38.43 for the average of the corresponding week for the past five years. Five hundred and eighty-one of the deaths were in children under five years of age, and 449 of these in children under one year. The number of births during the week was 1,141, and this apparent increase is no doubt due in some measure to the special efforts which the Health Department has lately made to secure more complete returns of births from physicians and midwives.

**ELECTROCUTION.**—In connection with the certificates of the execution of the four criminals at Sing Sing, which the warden of the prison, in accordance with the new law, has forwarded to the County Clerk, there has now been published a report of observations made by Drs. Carlos F. McDonald and Samuel B. Ward, who served as the official physicians at the execution. This report is, in part, as follows:

"In each case unconsciousness was produced instantaneously by the closure of the circuit, was complete, and persisted without interruption until the heart's action had entirely ceased and death had certainly occurred. In each case death was manifestly painless.

"In compliance with the statute, an autopsy was made in each case as soon as practical by Dr. Ira T. Van Giessen, of New York, in our presence and under our supervision, with the result of revealing the same gross changes in the blood and tissues previously observed in cases of death by the strong electric currents. Specimens, especially of the blood and of the nervous system, were taken by Dr. Van Giessen, for the purpose of careful microscopical examination, and the results will be forwarded to you as soon as such examinations are completed.

"In conclusion, allow us to congratulate you on the completeness in all their details of all your preliminary arrangements, on the uniform good order and decorum which prevailed during the trying ordeal, and on the resulting demonstration of the rapidity and painlessness of this method of inflicting the death penalty. The experience of to-day has proved to our satisfaction that this method is superior to any other yet devised."

**STERILIZED MILK FOR THE POOR.**—Sterilized milk is now being furnished to the poor on a large scale by the Eastern Dispensary on the East side of the city, and by the Greenwich Dispensary Association on the West side. At the latter institution, some of the milk, properly diluted and prepared for young infants, is supplied in feeding bottles, with directions for using blown in the bottles.

#### Miscellany.

#### MEDICO-LEGAL POINTS IN THE "FRENCHY" MURDER TRIAL.

This trial was extraordinary, not only on account of the peculiar nature of the crime, but on account of the character of the medico-legal evidence. The conviction of the prisoner was apparently largely due to the results of the chemical analysis of stains found on his person and clothing. The prisoner was indicted as George Frank. He was also known as "Frenchy." He was born on the northern coast of Africa. The nature of the crime was so suggestive of the work of "Jack the Ripper," that a remote possibility was suggested that he was indeed that well-known character. Dr. Austin Flint, one of the expert medical witnesses, has published what might be called a preliminary account of the case<sup>1</sup> the principal facts of which are as follows.

Shortly after midnight on the night of April 23-24, Carrie Brown, known as "Shakespeare," an abandoned woman, came to a low resort known as the East River Hotel, in the city of New York, and went to Room No. 31 with a man who was not the prisoner. This man disappeared during the night and has not been found up to the present time. In the hotel are several rooms on either side of a hall. The prisoner came to the hotel alone about 1 A. M. of the same night. He went with a candle to Room No. 33, across the hall from Room 31. About 5 A. M. the prisoner was seen to leave the hotel. About 10 A. M. the body of the murdered woman was found on the bed in Room 31. The lower part of the abdomen was slashed open, and several inches of the lower part of the ileum were cut out completely and left in or near the body. Other parts of the ileum were cut open, and one ovary was pulled out. The stomach and large intestine were not injured. An ordinary case-knife, broken and sharpened to a point and stained with blood, was found near the body. The bed-ticking under the body was soaked with blood. Three or four spots of blood were found in the hall between Room 31 and Room 33. A spot of blood as large as a dollar was found on the bed, and a spot of about the same

<sup>1</sup> New York Medical Journal, July 11.

size on a wooden chair in Room 33. Bloody finger-marks were found by the side of the door of Room 33 and on the wall near the door.

The murdered woman had said to a female acquaintance on the afternoon of April 23d that she had eaten nothing for several days. On that afternoon she took a glass of beer and a cheese sandwich and some corned beef, raw cabbage, and pickle from a "free lunch" counter. The prisoner had been in the habit of going to the hotel with women, and had frequently left his room, tried the doors of other rooms, and sometimes had gone into other rooms and remained awhile. The deputy coroner, testified that the murdered woman had died of strangulation. The prisoner was arrested the night after the murder. His shirt and both socks were stained with blood. Four days after the arrest matters were taken from beneath the finger-nails of the prisoner, which were unusually long.

The theory of the prosecution was that the prisoner had taken Room 33 for the purpose of entering other rooms during the night and gratifying his passions with women whom he might find alone; that he had entered Room 31 at some time during the night, and had found Carrie Brown after her male companion had left her; that he had taken her by the throat and strangled her, and then mutilated her as described. The theory of the defence was that the blood on the prisoner's shirt was from a woman with whom the prisoner had had connection the night before the murder during her menstrual period.

The verdict of murder in the second degree was reached on circumstantial evidence alone. The evidence which convicted the prisoner was largely that the various specimens presented blood mixed with matters which must have come from the small intestine, and which, by no reasonable theory, could be on the prisoner's clothing and person unless they came from the body of the murdered woman. Preparations were made from several stains in many of which, for instance, matters under prisoner's nails, front flap and right sleeve of shirt, wood from door, socks of prisoner, knife found in Room 31, bed-ticking and sheet from Room 31,—blood was found with more or less admixture of the following: biliary coloring matter unchanged; fat globules and crystals; tyrosine; cholesterol; triple phosphates; columnar epithelium; eggs of round worms; starch granules; partially digested muscular tissue, with a few fibres perfect, and partially digested vegetable matters; molecular detritus.

A record of the autopsy, showed that a portion of the lower part of the ileum had been cut out, the large intestine being uninjured. The case actually turned upon the distinction between the contents of the ileum and the feces, for it was the general opinion, at least of those connected with the prosecution, that this was the fatal point against the prisoner, as feces, especially in persons of filthy habits, might have been derived from sources other than those alleged. The opinion of the author, that the matters were from the small intestine, was based mainly on the presence of tyrosine and bilirubin. Relying upon the presence of these two substances taken in connection with the fact that the small intestine was cut and the large intestine uninjured, and that there was no part injured that could have furnished tyrosine, the conclusion was reached that the matters mixed with the blood, in the specimens which he examined, were practically identical and that they came from the ileum.

## THERAPEUTIC NOTES.

**VOMITING AFTER CHLOROFORM.** Lencvitch<sup>1</sup> emphatically draws attention to a method for arresting obstinate vomiting which so frequently occurs after chloroform anesthesia, especially in cases of abdominal section. The method consists in thoroughly washing out the patient's stomach with a lukewarm 0.5 or 1 per cent. solution of soda.

**HÆMORRHOIDS.** — Preismann<sup>2</sup> recommends the application of pledgets of cotton soaked in the following:

R Potassii iodidi . . . . . 3 ss to 3 i.  
Iodi . . . . . gr. iii to gr. xv.  
Glycerin . . . . . 3 i. M.

**LACTIC ACID IN DIARRHŒA.** — At a recent meeting of the Société Médicale des Hôpitaux, Professor Hayem communicated a note on the above subject. He prescribes as follows:

R Lactic acid . . . . . 10 to 15 gram.  
Syrup of mulberry . . . . . 500 gram.  
Water . . . . . 500 gram. M.

Half a glass to be taken at a time between meals.

Professor Hayem would recommend the same recipe as a prophylactic, and as a curative agent in epidemic cholera.<sup>3</sup>

**PUERPERAL ECLAMPSIA.** — Perron<sup>4</sup> has obtained good results by the subcutaneous injection of ether.

## Correspondence.

### "MORTON'S AFFECTION OF THE FOOT."

Boston, July 18, 1891.

MR. EDITOR:—I was much interested in reading Dr. E. H. Bradford's recent article<sup>1</sup> upon "Morton's Affection of the Foot," as I was myself an acute sufferer from this form of neuralgia for a number of years. I tried various forms and sizes of shoe without relief, until Mr. Hinckley, of 101 Charles Street, finally made me a shoe which I could wear with comfort. Under his skillful workmanship I have never had a recurrence of the pain; and he has also cured several of my patients whom I have sent to him with similar trouble.

Yours sincerely,  
G. M. GARLAND, M.D.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JULY 11, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from					
				Infectious diseases.	Consumption.	Diarrhoeal diseases.	Scarlet fever.	Diphtheria and croup.	
New York	1,515,391	957	581	39.31	9.25	29.43	3.12	3.43	
Chicago	1,029,850	—	—	—	—	—	—	—

Deaths reported 3,157; under five years of age 1,825; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,119; consumption 297, acute lung diseases 181, diarrhoeal diseases 911, diphtheria and croup 80, scarlet fever 23, typhoid fever 27, measles 25, cerebro-spinal meningitis 13, whooping-cough 11, malarial fever 8, erysipelas 5.

From typhoid fever Philadelphia 11, New York 4, Baltimore, Cincinnati, Nashville and Charleston 2 each, Brooklyn, Boston, Washington and Springfield 1 each. From measles New York 13, Brooklyn 5, Fall River 3, Washington, Portland, Lowell and Pittsfield 1 each. From cerebro-spinal meningitis New York 5, Brooklyn 3, Lynn 2, Boston, Washington and Chelsea 1 each. From whooping-cough New York 3, Brooklyn and Washington 2 each, Philadelphia, Baltimore, Milwaukee, Charleston and Cambridge 1 each. From malarial fever New York 5, Baltimore, Charleston and New Bedford 1 each. From erysipelas New York 2, Philadelphia, Brooklyn and Cambridge 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,105,108, for the week ending July 4th, the death-rate was 17.7. Deaths reported 3,157; acute diseases of the respiratory organs (London) 257, whooping-cough 57, diarrhoea 75, measles 67, scarlet fever 27, fever 23, diphtheria 20.

The death-rates ranged from 13.1 in Birkenhead to 24.6 in Wolverhampton, Birmingham 17.3, Bradford 16.1, Hull 17.1, Leeds 17.7, Leicester 15.7, Liverpool 20.2, London 16.8, Manchester 23.1, Newcastle-on-Tyne 17.8, Nottingham 13.2, Sheffield 17.5, Sunderland 20.3.

In Edinburgh 20.6, Glasgow 19.8, Dublin 21.1.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 11, 1891, TO JULY 17, 1891.

Assistant Surgeon PAUL R. BROWN, U. S. Army, leave of absence extended one month.

Assistant Surgeon W. B. BANISTER, U. S. Army, granted leave of absence for fourteen days.

Assistant Surgeon JOHN J. COCHRAN, U. S. Army, leave of absence, on surgeon's certificate of disability, extended three months.

Surgeon BERNARD J. D. IRWIN, U. S. Army, relieved from duty at St. Louis, Mo., and ordered to Chicago, Ill., for duty as medical director, Department of the Missouri.

Major ELY McCLELLAN, surgeon, heretofore assigned to duty in the Division of the Missouri, will report to the commanding general, Department of the Missouri, for assignment to duty as attending surgeon, Headquarters Department of the Missouri, and examiner of recruits at Chicago, Ill.

Colonel CHARLES PAGE, surgeon, heretofore assigned to duty in the Division of the Atlantic, will report to the commanding general, Department of the East, for assignment to duty as medical director, and Lieutenant-Colonel CHARLES T. ALEXANDER, surgeon, will report for assignment to duty as attending surgeon, New York City, N. Y.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 18, 1891.

L. W. ATLEE, passed assistant surgeon, ordered to the "Independence."

JAMES SHIRLEY HOPE, appointed an assistant surgeon in the Navy from July 10, 1891.

WM. MARTIN, surgeon, detached from duty at the marine rendezvous, San Francisco, Cal., and from special duty in that city, and granted leave until September 15th, and then to be placed on waiting orders.

M. H. CRAWFORD, passed assistant surgeon, detached from the "Independence," and ordered to duty at the marine rendezvous, San Francisco, Cal., and to special duty at that city.

## APPOINTMENT.

Dr. J. P. Crozer Griffith, Professor of Clinical Medicine in the Philadelphia Polyclinic, has also been elected Clinical Professor of the Diseases of Children in the University of Pennsylvania.

## DEATHS.

WILLIAM H. TAYLOR, M.D., M.M.S.S., of New Bedford, died, July 20th. Dr. Taylor graduated from the University of the City of New York in 1876. He was Medical Examiner, a member of the Massachusetts and the New York Medical-Legal Societies, and Surgeon to St. Joseph's Hospital.

J. F. GROENEVELT, M.D., Assistant Surgeon of the Marine-Hospital Service, died of yellow fever, June 29th, while on duty at the Gulf Quarantine Station.

J. L. VANDERVOORT, M.D., for more than fifty years Librarian of the New York Hospital Medical Library, died, July 20th, aged eighty-two.

F. H. POTTER, M.D., of Buffalo, N. Y., Clinical Professor of Laryngology at the University of Buffalo, died, July 16th, aged thirty-one.

T. NAYLOR BRADFIELD, M.D., of Newark, N. J., died, June 28th, aged forty-nine.

SAMUEL SANIS, M.D., of Darien, Conn., died, July 14th, aged seventy-four.

DAVID MATTHEWS, M.D., died in New York, July 9th, aged sixty.

## BOOKS AND PAMPHLETS RECEIVED.

Hysteria. By A. F. A. King, M.D. New York: William Wood & Co. 1891.

Bloodless Amputation at the Hip. By Emory Lanphear, M.A., M.D., Kansas City. Reprint. 1891.

Practical Intestinal Surgery. By Fred B. Robinson, B.S., M.D. Vol. I. Detroit: George S. Davis. 1891.

Vacation Time, with Hints on Summer Living. By H. S. Drayton, M.D. New York: Fowler & Wells Co. 1891.

Bibliographie der Klinischen Helminthologie. Heft I. Echinococcus cysticus hes. von 1877-1880. Von Dr. J. Ch. Huber. Munchen: J. F. Lehmann. 1891.

Contributions to the Pathology of Infantile Cerebral Palsies. By H. Sachs, M.D., Professor of Mental and Nervous Diseases in the New York Polyclinic. Reprint. 1891.

Atlas of Clinical Medicine. By Byron Bramwell, M.D., F.R.C.P., Edin., etc. Volume I, Part I. Edinburgh: Printed by T. & A. Constable, at the University Press. 1891.

Diseases of the Mid-Brain Region, with Special Reference to Ophthalmoplegia, and a Note on Post-Hemiplegic Ataxia. By H. Sachs, M.D., Professor of Mental and Nervous Diseases in the New York Polyclinic. Reprint. 1891.

## Lecture.

NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

(Continued from No. 4, page 76.)

**Classification:**—In its acquired form, in a previously healthy organism, it is a primary or a secondary neurosis,—primary when it is due to the immediate effects of nervous over-strain, or to a primary and toxic disorder of nutritional processes,—and secondary, when consequent upon other diseases having a general pathological diathesis with its peculiar exhausting and toxic influences. There is an acute stage, in which the double elements of causation are always present: exhaustion with inanition, and toxicity. It is important to remember that the acute stage may continue for years with a series of exacerbations, under recurrences of the dual causes, and the tendency of nature to effect recovery, which may be finally established. In the chronic stage there has supervened the “molecular or chemical variation” manifested as “an exhausted or changed nutritional power” in nerve-cells,—a condition which may sometimes represent a partial recovery. There may be, in this stage, good blood, good muscles, a well-working mechanism, fairly good health, and physical comfort within lessened limits of nervous strength. The word chronic implies more than duration,—the transition is complete to the stage of permanent change, and the “constitutional predisposition” is fully acquired and established. It is this predisposition transmitted, which constitutes hereditary neurasthenia. In this condition all the forms may occur in all degrees of severity, and may be ameliorated by prophylaxis; it may even exist so quiescent and concealed that it appears to have acute and active manifestations followed by recovery.

**Autogenous Toxic Substances.**—In support of these conclusions, there would seem to be no unreasonable stretch of inference in such an analysis of the well-known facts of the autogenous production of toxic substances, and of their action in the causation of Neurasthenia. Moreover, these facts, and much past conjecture, are now being reduced to scientific order by the discoveries that have established the principle of autogenous disease. It is shown that as the poisons of infectious disease are the chemical products of the action of bacteria upon organic matter, so there are like poisonous substances that regularly result from the chemical changes in non-infectious tissue-metabolism within the body. Just as ptomaines are noxious to the micro-organisms producing them, so are the normal cells injured when the products of their own activity accumulate about them. The discovery, in some of these animal alkaloids (ptomaines and leuconaines), of the chemical poisons that have long been sought, is of special interest in the study of neurasthenia. Some of the substances, not alkaloids, formed in the alimentary canal in the processes of digestion, are powerful poisons; the albumoses and peptones normally produced in the breaking up of the proteids in the food. As Vaughan<sup>28</sup> states it, in discussing the

chemical factors in the causation of disease, “it matters not whether the proteid molecule be broken up by organized ferments (bacteria), or by the unorganized ferments of the digestive juices—by the cells of the liver, or by those still unknown agencies which induce metabolic changes in all the tissues; in all cases poisons may be formed. These poisons will differ in quality and quantity according to the force which acts.” A number of observers have shown that the peptones may have an intensely toxic action, should they reach the general circulation unchanged.

Hare<sup>29</sup> explains the symptoms of biliousness as not depending upon the changes in the bile, but upon failure of proper digestion in the stomach and intestine, coupled with the development of irritative decomposition-products including a large number of poisonous alkaloids. Normally these do not form in the presence of the antiseptic bile which counteracts the action of the bacteria introduced with the food and is always to be found in the intestinal canal. The disorder of the hepatic function of destroying all poisons of an organic character permits the entrance into the general circulation of these substances, some of which act as *curare*, *digitalis*, *atropine*, *muscarine* and *picrotoxine*; and the number of these compounds is indefinite. He suggests that when symptoms of such poisoning appear, relief may be afforded by the known antidotes for those drugs.

Brunton<sup>30</sup> describes some symptoms of dyspepsia, generally occurring about two hours after meals, as resembling *curare*-poisoning of the peripheral ends of the motor nerves. These are “muscular relaxation,” “a curious weight in the legs and arms” which “feel heavy like lumps of lead.” He says that the “melancholy and depression of spirits,” associated with disorder of the liver, depend upon noxious substances passing into the general circulation because the liver fails to arrest them. He notes the “hypochondriasis and depression of spirits” associated with oxaluria, when “the patients complain of incapability of exerting themselves, the slightest exertion bringing on fatigue.” Severer cases in the asylums have been described as the insanity of oxaluria. But Brunton says these symptoms may occur without oxaluria, and he conjectures the presence of some poison in the blood.

Halliburton<sup>31</sup> describes choline and neurine as ptomaines which may also be formed during life as leuconaines in the metabolic processes. Choline is of great importance as a type of these alkaloids, and neurine is closely related to it. Both act like *curare* on the end-plates. Muscarine, the alkaloid from poisonous mushrooms, is of the same class, and can be obtained also from choline by oxidation; it acts directly upon the muscular tissue itself. All these are powerful poisons, and are antagonistic to atropine in their special action on the heart and glandular system. Choline was first obtained by Strecker from bile, but choline and neurine are among the chief products of decomposition of lecithin. This important constituent of nervous tissue is found also in muscle, blood, and wherever cellular elements exist in the body; it is also in eggs, milk, cheese and other forms of food.

In the changes of nitrogenous metabolism from nervous and muscular tissue through the complex series of transition-products to the end-products discharged

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.<sup>28</sup> Jour. Am. Med. Assoc., May 16, 1891, p. 16.<sup>29</sup> Practical Therapeutics, 1890, p. 37.<sup>30</sup> Disorders of Digestion, 1886, pp. 42, 47.<sup>31</sup> Chemical Physiol. and Pathol., 1891, pp. 178, 530.

as urea, uric acid, etc., these are notably augmented after excessive muscular work. There are a number of the intermediate substances which are credited with possessing an intensely poisonous action; this includes the familiar phenomena of the still undetermined uramic poisoning. According to Gautier,<sup>82</sup> in the cycle of changes in the normal tissues of the body, there is constantly going on the formation of leucamines and their subsequent destruction by oxidation before they have accumulated in sufficient quantity to produce poisonous effects. Hydrocyanic acid plays a very important part in the molecular structure of these bases. One of them, for example, xantho-creatine, studied by Gautier, is poisonous, producing in animals, depression, somnolence, and extreme fatigue; and it appears in physiologically active muscles along with creatinine. Monari has found this base in the aqueous extract of the muscles of an exhausted dog, and also in the urine of soldiers tired by several hours' walk.

The formation and excess of uric acid in the body, and its elimination, have been among the most thoroughly studied of all the toxic conditions. Whether it is due to an excessive formation in the liver, a defective excretion by the kidneys, or to some abnormal state of the nervous system, the many observers agree to its production of the marked symptoms noted by Murchison, among which are lassitude, headache, vertigo, insomnia, depression of spirits, irritability of temper, etc. Garrod ascribes its retention to failure of excretion; and Haig<sup>83</sup> has shown that, being formed by normal processes, its storage in the body, or excretion, are greatly influenced by the comparative alkalinity of the blood, which may be made to vary at will, within considerable limits, by the kind of food, the process of digestion, and the use of drugs. Thus the ingestion of acids, etc., reducing the alkalinity of the blood, and therefore its solvent power, causes the accumulation of uric acid in the tissues. The blood being freed of uric acid, there is diminished arterial tension, better cerebral nutrition, and sometimes a temporary sense of well-being and exaltation. This condition of the circulation is opposed to the elimination of uric acid, and favors storage and retention in the tissues, tending to later trouble. But in such cases, when from any cause there is increased alkalinity of the blood, the uric acid is more soluble, and its presence in the circulation produces the mental symptoms described.<sup>84</sup> Macfarlane<sup>85</sup> believes that the lessened alkalinity of the blood is the important cause of the disorders of sleep in the gouty, as being dependent primarily upon mal-nutrition of the cerebral cells, which renders them irritable and responsive to faint impressions. Cells imperfectly deprived of their detritus do not appear to take up oxygen readily, and consequently they cannot be adequately nourished; they eventually assume a state allied to that met with in neurasthenia.

According to Haig, uric acid in the blood contracts the arterioles and capillaries all over the body, producing coldness of the surface and extremities, and the headache of migraine as a local, vascular effect of uric acid. With less or effects there are mental depression, dulness, and inability for mental effort. Van Jakseh,<sup>86</sup>

using the term uric-acidemia, has recently found that uric acid accumulates in the blood not only in gout but in anamic conditions, and considers that the cause of its appearance is defective oxidation. Many observers have attributed gout to the nervous system. Sir James Paget has pointed out that gout mainly affects the sensory parts of the nervous system. These studies show, in respect to this one toxic influence, that its presence in the body, in other conditions as well as the gouty, bears an important relation to the disorders of the nervous circulatory and nutritional processes,—and to that striking symptom of a sub-normal surface temperature which is persistent in some forms of neurasthenia; it also produces characteristic mental symptoms and disturbance of the sensory functions.<sup>87</sup>

The way in which repeated muscular contraction causes what is known as fatigue, is however very uncertain. In regard to the effect of the accumulation of products of combustion, the increased acidity of fatigued muscles has been noted by numerous observers since Ranke<sup>88</sup> pointed out the depressing effect on muscular irritability produced by all acids,—the carbonic and lactic among others, the muscle being alkaline in a state of rest. This excess of acid manifests itself subjectively by the sensation of fatigue, followed by sleep. The revival of exhausted muscles, upon renewal of the blood stream, is due probably both to the removal of the acids and other products of contraction, and to the fresh supply of oxygen,—the chief end-products of carbon and hydrogen metabolism being eliminated by several channels, expired air, sweat and urine. Mosso<sup>89</sup> considers that the poison which causes the symptoms of exhaustion is probably not carbonic acid, but a substance produced in small quantities of an alkaloid nature.

In regard to the results of exercise of nerve tissue it is believed by some that fresh brain, cord, or nerve, has normally an alkaline reaction. All observers, however, agree on the most important fact, that acidity, whether present initially or not, increases on activity, and on death, and is probably due to lactic acid. This inevitably suggests a comparison between nerve and the closely related tissue, muscle. The only known chemical changes during activity of nerve tissue is the increase of acidity; the only known physical change is an electrical one, other than those shown by the demonstrations of Hodge. Some light may come, from such studies, upon the darkness of our knowledge with regard to the essential molecular changes that attend nervous activity. In the chemical reactions the great importance of a healthy blood-supply is noteworthy here; the deprivation of the oxygen it affords means an abolition of all the higher cerebral functions, such as consciousness and volition.<sup>90</sup>

There can be little doubt that certain febrile conditions are autogenous; they may be due to excessive formation of poisons in the body, or an accumulation of these through deficient elimination. Bouchard has shown that the urine excreted during the hours of activity is much more toxic than that excreted during the hours of rest. Both physical and mental labor are accompanied by the formation of the poisonous substances which will accumulate if the hours of labor are

prolonged and those of rest shortened.<sup>41</sup> As a result of deficient elimination, "fatigue fever" is not uncommon in its milder forms, with its symptoms of impaired appetite, mental and physical "irritability," restlessness, insomnia or fitful and unrefreshing sleep, and an excited brain that will not rest. In a severer degree this self-produced condition is the "fever of exhaustion"; and this leads up to the deadly typhus, which is the highest expression of the poisoning of the organism by itself or by contact with others under like conditions.<sup>42</sup>

The general truth of this matter is well summed up by Aitken<sup>43</sup> when he says that "the healthy living organism may become poisoned (gradually and more or less slowly) by the accumulation within itself of deleterious substances normally elaborated. Hence the slow and insidious onset of much ill-health; and from which recovery is correspondingly slow." The few examples cited serve to show the nature of the evidence, and that we have constantly to deal with definite toxic influences in the processes of nutrition and the discharge of energy in the organic mechanism. It is true that we have as yet little precise knowledge of these toxic substances, and of their effects upon the nervous system. Many of those obtained are probably formed by the action of the reagents used in the analysis, when their existence in a free state, in healthy tissue, is very doubtful. But though the science is yet in its infancy we know enough to recognize the immense clinical importance of studying the chemical elements whose positive influence in the production of nervous symptoms must now stand as an unquestioned fact. It must be remembered also that we are still compelled to study functional "activities," and disordered conditions of which we can find no trace in the organism.

The study of the general organic mechanism, so far, shows that it may be conceived as made up of many minor mechanisms which may be studied as represented by their activities. Some general truths have been reached in regard to all of them as to their structure, their co-ordinations, and the results of their functional exercise. These conclusions are in support of my first proposition, to the effect that, when the mechanism is put into use, physiological activity and toxicity always occur together, and that the condition thus jointly produced has its first expression in normal fatigue. Moreover it appears that in pathological fatigue or nervous exhaustion, which constitutes neurasthenia, there results from excessive use and inanition a condition of "excessive irritability and weakness" of the nervous system. There is also, in acute neurasthenia, always an increased toxicity, by its accumulation in fatigued areas, and often by general fatigue and auto-intoxication through disordered nutritional processes.

(2) *Mental Elements in Normal and Pathological Fatigue.*—It is next in order to make a practical application of general truths more precisely to the nervous and mental mechanisms, and their special disorders in neurasthenia. This leads to my second proposition, that to properly study our problem we must take into account the nature and manner of production of the mental symptoms common to nervous exhaustion and insanity. This brings out the main purpose of this study of the relations between mind and body:—to

show how it is that the mental symptoms furnish a ready index of the fatigue and auto-intoxication of nerve and muscle tissues, as a guide for diagnosis, prophylaxis, and treatment; and also to show how the general symptoms of nervous exhaustion can be better understood by a proper interpretation of the mental symptoms. The acute, acquired form of neurasthenia will therefore be first considered with reference to the mental symptoms, to show what they are, and how they are produced.

All observers agree that the symptoms of neurasthenia are largely subjective. There are objective signs, but the physician mainly depends upon the patient himself to tell how he feels. Every physician also learns to qualify such statements according to his estimate of the individual and his mental state, under the bias of the characteristic "hopelessness" and "worry," or even of the less intense "depression of feeling." These symptoms pertain to the state of the feelings, and constitute the emotional tone, in its intimate dependence upon bodily states which afford a general sense of comfort or discomfort,—of well-being or ill-being, more or less persistent. This is quite independent of the intellect, and the passing feelings which are normally attendant upon pleasing or painful ideas. These disorders of the feelings and the emotional state constitute one distinct group of mental symptoms.

All the writers on this subject have also given prominence to the striking clinical manifestations of "inability to concentrate the mind,"—the weakening of the power of attention. Here is another important group of symptoms that represent disorders of the intellectual activities and the voluntary power. The most prominent of these, as a sensitive index of nervous fatigue and exhaustion, is the attention.

#### *The Primary Data of Mental Activity,—two groups.*

—All these mental activities have to deal with sensations as furnishing the primary data of their operations. There are two groups also of these sensations:—the first are the general organic sensations, not intense enough ordinarily to pass over the threshold of consciousness, but they constitute the vast subconscious inflow of minor sensations through all the sensory channels that lead to the sensorium from every tissue and organ, and from every peripheral mechanism, nervous or muscular, in the body; the second are those we are conscious of as presented through the special senses and that stand in the mind as perceptions, ideas and memories:—these are the data of consciousness. The great complexity of this matter can be made intelligible by taking a little time and patience to grasp some general principles, and to reduce the complex elements to an orderly arrangement in our conception of the mental mechanism.

#### (1) *Organic Sensations and the Emotional Tone.*—

The organic sensations in the subconscious mechanism, demand first consideration as best revealing something of the mystery in the relations between mind and body, and the genesis of the mental symptoms in neurasthenia. These sensations, proceeding from all the states of the body, are in some degree and form represented in the sensorium. They constitute the sense of body,—the sense of personality.<sup>44</sup> The line cannot be strictly drawn between the conscious and the subconscious activities, as to these organic sensations. Many of the sensations received through the special

<sup>41</sup> See Vaughan and Novy, op. cit., p. 263.

<sup>42</sup> See Aitken: *The Animal Alkaloids*, 2d Ed. 1889, p. 28.

<sup>44</sup> Ribot: *The Diseases of Personality*, trans. Chicago, 1891.

senses and giving knowledge of the outer world, enter a passive consciousness, as the ticking of a clock that is not consciously perceived unless it stops, or attention is turned to it. There are still weaker sensations, coming through the special senses, of which we are not conscious. In like manner, but in reverse order, the great mass of the organic sensations are normally unperceived, but some of them may be intensified enough, as by some disorder, to enter the field of consciousness. Those arising from the trophic, and minor inhibitory mechanisms, are among the most subtle and unfelt, as are those from vaso-motor changes in the general and local circulation which are most important in their influence upon mental states. But even among these, the inner tingling sensations, followed by general chilliness and external pallor upon a sudden idea of great danger, are probably due to the swift vaso-motor constriction. There are also the normally unperceived, though incessantly repeated sensations, which provoke and accompany the respiratory movements. They may arise also from the state of the muscles after exercise, even when inactive, giving the feeling of fatigue and exhaustion; or in an opposite condition may afford a general sense of vigor. The muscular sense is a stronger representation of the organic sensations that are sometimes classed with the special senses. Hunger and thirst are not localized sensations, but result from a discomfort of the whole organism, being connected with the state of nutrition.<sup>45</sup>

*Sense of Well-being.*—These normally latent or obscure sensations, low in intensity but great in volume, are persistently flowing inward beneath the fewer but relatively intense and transient sensations from the special senses. In the healthy organism, refreshed and vigorous, there is an equilibrium of physical sensations, or a multitude of agreeable feelings attendant upon the exercise of normal power. This physical state produces a mental sense of well-being; the persistence of this will give its special character to the physical and mental habitude, or the personality of the individual.

### COMPRESSION IN THE TREATMENT OF ANEURISM, WITH THE DESCRIPTION OF A NEW APPLIANCE.<sup>1</sup>

BY H. H. A. BEACH, M.D.,

*Leading Surgeon, Massachusetts General Hospital.*

IN asking for the attention of the Society upon a subject that has already received the widest discussion from some of the ablest writers in the profession, I will not repeat the arguments for and against the treatment by compression as opposed to ligation, believing that you are already familiar with them. It may be conceded, however, that in view of the greater chances of a rapid union of wounds without suppuration, through the employment of rigid antiseptic precautions, the mortality from the operation alone, on arterial trunks, has been much reduced in the past

thirty years, and cannot be fairly compared with the statistics of compression for the same period. A comparison of the statistics of amputation and ligation of principal arteries compiled twenty-five years ago (see those of Mr. Bryant and Dr. Norris respectively) shows almost as great a mortality from ligation of the femoral artery as from amputation of the thigh. The mortality of the Hunterian operation to the year 1870 was 18.7 per cent. After that it was reduced to 15.6 per cent., and from 1875 to 1879 it declined to 8.57 per cent.<sup>2</sup> In six London hospitals it reached 23.08 per cent.

On the other hand, the Hunterian operation involves the most serious risk to life and limb through a factor which is independent of an aseptic wound, and that is gangrene. Of 53 fatal cases of ligation of the femoral artery for other reasons, reported by Norris, 23 died of that disease. In striking contrast to the foregoing clause is the following extract, from the report by Mr. Hutchinson, in the *London Medical Times*, 1856:<sup>3</sup>

In 46 cases of popliteal aneurism treated by pressure, 24 were cured. Of the remaining 22, in whom the artery was tied, two only died of gangrene, while of ten other cases where the vessel was tied, without preliminary compression, three died of gangrene.

If important changes in methods of compression have developed from year to year, it is clear that they have not kept pace with the advantages gained through an aseptic wound treatment when employed in the ligation of arteries. Of 148 cases of popliteal aneurism collected by Barwell,<sup>4</sup> where various forms of compression had been employed, 80 of them were failures. Of 47 cases treated by the Esmarch bandage, 20 were unsuccessful, and required other treatment. Another group of 90 patients, also collected by the same writer, gave 34 failures; and of 91 cases treated by the flexion method, 49 were unsuccessful. Of 22 cases, including various methods of treatment at the Massachusetts General Hospital, between the years of 1821 and 1864, the percentage of cures was 54.44. They included six cases treated by primary ligation of the femoral artery, three by compression, one by compression and secondary ligation of the femoral artery, and in two instances the sac was incised and both ends of the artery tied. Two patients left the hospital relieved by compression and secondary ligation of the femoral, and two others that had been treated by compression alone. Of the six deaths, two resulted from ligation of the femoral, one from incision into the sac and with both ends of the artery tied, one from compression, one from compression and kneading of the sac, and another from compression and secondary ligation of the femoral artery.

The large number of failures in the treatment of popliteal aneurism by compression, as compared with ligation of the femoral artery, excluding the advantages of the antiseptic method, point to some radical defect in the application of compression. Upon examination of the records of various methods, that of Mr. Todd, of Dublin, as published by Holmes, attracts immediate attention, for it includes a principle that I believe is fundamental in the successful treatment of aneurism, whether applied accidentally or with intention. To lessen the risk of gangrene, Mr. Todd recommended a preliminary pressure on the femoral artery

so as to cause a dilatation of its collateral branches. This practice was followed out for some time, and then became merged in the general one of continuous compression without ligation of the artery, in which the Irish surgeons were particularly successful, Mr. Holmes quoting a series of 25 cases with but one failure.

There can be no question that the cure of a popliteal aneurism, either by ligature or compression with preservation of the leg, includes the development of an adequate collateral circulation, and that the development of such a circulation depends upon the number of anastomosing branches (which are known to vary), the degree of constriction to which the limb may be subjected, the quality of the blood and the skill with which compression is applied to the main arterial trunk, and last, but not least, the soundness of the arterial system and the propelling power of the heart. The first and last two factors cannot be definitely estimated before subjecting the patient to the test which a complete blocking of the artery furnishes. Assuming that to be done with a ligature (unless applied provisionally), a certain number of chances against recovery must be taken with no possibility of changing the course of treatment. Should gangrene follow the application of the ligature, our only recourse is amputation, and even that provision may be denied the surgeon.

With an efficient apparatus for compression, the flow of blood may be regulated by the necessities of the limb, as shown by temperature and color. One can hardly appreciate the tremendous tension to which vessels no larger than the capillaries are subjected in the establishment of a collateral circulation, without the careful dissection of parts so involved. It is easy to understand why ulceration of the main trunk may occur at the point of ligation from such pressure, and so end the patient by hemorrhage before a cure of the aneurism has been effected. My attention has been directed to this subject through various experiences in the treatment of aneurisms, but more particularly in the year 1875, when, through the kindness of Dr. Buckminster Brown, I had the opportunity of making the post-mortem examination of a patient of his, who had died six years after the cure of a femoral aneurism by direct compression.<sup>5</sup>

A careful study of this preparation was convincing as to the amount of pain which was likely to follow an interruption of the arterial current through the great distension of the smallest vessels that could ramify between the nerve fibrils and in the sheath surrounding the anterior crural and sciatic nerves. Such a distension should cause about the same amount of pain, whether produced by ligature or compressing pad. It is of a different character from that caused by the application to the skin of hard, unyielding pads maintained in position by a mechanism equally rigid and unyielding. That such pressure without anesthesia should be unbearable, it is not difficult to understand, whether produced by fingers or pads; also, that the only substitute for it is the employment of more time in the process of cure, by a compression that can be borne without anesthesia, or the production of sloughing skin.

In the construction of apparatus for the treatment of popliteal aneurism, much ingenuity has been shown in the application of pads and weights with and without

springs of various kinds, wet sponges, hollow rubber balls, etc., all of which show the desire to accommodate the necessary amount of compression to a preservation of the soft parts. In considering the various appliances for saving pain and sloughing skin in *other* surgical cases, the protection and equable distribution of pressure that can be had through the application of a rubber water-bag occurred to me. Its use was suggested by the relief which I had known to follow such an appliance in the support of the heel, in fractures where the pain was considerable, in the bliss which comes to those afflicted with burns and scalds who must lie upon their ulcerated surfaces, and to the efficiency with which trusses equipped with such pads support a hernial protrusion.<sup>6</sup> The advantages suggested by the new pad were a steady and equable pressure, easily controlled and adapted to the requirements of many cases, comfort to the patient, and security from the production of sloughing. It was a simple matter to test its efficiency by attaching it to the wooden ball of the Massachusetts Hospital tourniquet with which you are all familiar, and to apply it to the first case that should enter for treatment. Fortunately that case was a most unpromising one, and offered the severest test of the capacity of the instrument, as the following extract from the hospital records will show:

The patient, a negro woman of moderate intelligence, thirty-one years of age, entered the hospital with a history of syphilis, having had tertiary symptoms. For eight weeks she had suffered from pain in the popliteal space, for which she used liniments. Her leg had been swelling below the knee for four weeks, and a swelling had been noticed in the popliteal space within that time. She was unable to walk, nor could she extend the leg on account of the pain produced. She also suffered from constant pain which extended from the popliteal space into the foot. The knee was swelled, and a tumor the size of a hen's egg filled the popliteal space, and presented an expansile pulsation, which was transmitted to the muscles on either side of it.

Pressure on the femoral artery at the apex of Scarpa's triangle stopped the pulsation. The leg was raised on pillows, and the foot of the bed elevated for two days, to lessen the edema of the limb.

Compression was applied to the femoral artery at about the middle of the thigh, with the tourniquet and rubber water-pad covered with silk, as before described. An ice bag was placed over the knee, a fold of linen cloth between the pad and the skin, and the pressure regulated so as to diminish the circulation in the aneurism, but not to stop it entirely.

During the next four days the patient had considerable pain in the knee and foot, controlled by morphine. A marked diminution in the pulsation of the aneurism.

In the next six days the pressure easily arrests the aneurismal pulsation, without pain at the point of pressure. The patient complains of pain in the knee, and describes the return of sensation to the foot where before it had been numb. She is restless at times, and the pain easily controlled by morphine.

On the tenth day from the beginning of pressure the pulsation had ceased to be expansile. A single murmur could be heard over the inner surface of the knee, but none at the middle of the popliteal space.

Two days later the pulsation was very slight; the pressure was removed.

<sup>5</sup> For description of autopsy and specimen see Boston Medical and Surgical Journal, 1875 ("Femoral Aneurism").

<sup>6</sup> As manufactured by Messrs. Leach & Green.

For the following two weeks a very faint pulsation remained in the tumor, which was not in the least extensible. The pain in the knee stopped, and the oedema of the leg and foot nearly disappeared. The leg could be more easily extended.

One month following the removal of the tourniquet a slight fluctuation was detected at the most prominent point of the swelling.

Two days later pulsation reappeared, and pressure was reapplied to the femoral artery.

In two days the pulsation had nearly stopped again. At the point where fluctuation had been detected, the skin became progressively thinner until twenty-five days after, when the staining of the bed-linen with reddened serum suggested the necessity of opening the sac and turning out its contents.

A tourniquet was applied to the artery, the patient removed to the operating theatre, and the aneurism laid open by an incision of four inches. There was no evidence of suppuration, but the cavity of the aneurism, which was of the size of two fists, was filled with a firm and distinctly laminated coagulum, which had apparently by pressure caused an erosion of the aneurismal sac from within. The incision was prolonged to a point above Hunter's canal, and the femoral artery tied with silk at that point. The upper end of the vessel was partly filled with thrombus, the lower end completely plugged, and not requiring a ligature. There was some hemorrhage, which was checked without difficulty, the cavity carefully cleansed and packed with iodoform gauze. The patient rallied well from ether.

Five days later this dressing was removed, and the wound found closed by first intention, with the exception of the cavity of the aneurism, which gradually filled with granulations and healed, so that she was discharged from the hospital in a few weeks.

During that time she developed a troublesome bed-sore over the external malleolus, which was slow in healing, also specific symptoms which yielded to appropriate internal treatment.

I have seen her within a short time, one year following her admission to the hospital, and found her doing all of her house-work, the wound of operation having healed completely, and presenting a flexible cicatrix that permitted flexion of the limb with ease. She had a neglected ulceration on the lower part of the leg, which she did not think worth while to devote much attention to.

To summarize the case is to repeat that a well-regulated compression, applied continuously and at the same point to the skin of a syphilitic subject for twelve days, and for other shorter intervals afterwards, produced little or no pain at the point of pressure, and not the slightest irritability of the skin. That, notwithstanding the success of the compression in forming a truly laminated clot filling the cavity of the aneurism and developing an efficient collateral circulation, better material was needed than what could be furnished by a patient cachectic from syphilis, to consolidate the large mass of clot and insure its firm and permanent adhesion to an already largely distended aneurismal sac. To have attempted a ligation of the artery or a complete compression of the femoral at the very beginning of treatment, without having first developed a competent collateral circulation, would have, as nearly as I could estimate the chances, sacrificed the leg with gangrene. While the complete

success of the compression, without resorting to the method of Antyllus, would have been most gratifying. I am glad to present you with evidence so satisfactory of the value that the new appliance may have in cases uncomplicated with other diseases.

The apparatus, which is manufactured at a moderate price by Messrs. Leach and Green, consists of a steel base measuring eight by nine and a half inches, and uprights on each side measuring nine and a half inches. The latter are continuous beneath the base, and for stability are firmly riveted to it. Each upright supports a steel rod of one-quarter of an inch diameter. Upon the rods slides a light, but firm, carriage, which

can be fixed at any point by a thumb-screw. The carriage is perforated in its centre, and drilled to receive a screw of three-eighths of an inch diameter, carrying four threads to the inch, and measuring seven inches in length. It is fitted at the top with a thumb-piece, and at its bottom with the small rubber water-bag, already described, and measuring an inch and a half in diameter. It is easy to understand that, with the aid of carefully folded sheets and towels, the apparatus can be adjusted to a thigh of any size, and the pressure adapted to the requirements of the case. By unscrewing the nuts at the ends of the rods, the screw and the pad can be quickly removed to permit the adjustment of the thigh with the greatest comfort to the patient. A question might be raised as to the durability of the water-pad. I can only say that, having prescribed them for a number of years in the treatment of hernial tumors, I have never known one to rupture, even after long service.

**CHEAP FARES FOR PATIENTS.**—By a recent ordinance of the Bavarian Government patients in necessitous circumstances are granted a reduction of railroad fare in going to or from hospitals or other public medical institutions. They are henceforth to be charged at the same rate as the special third-class fares allowed to soldiers.

A CASE OF NEPHRECTOMY FOR INJURY OF THE KIDNEY.<sup>1</sup>

BY HOMER GAGE, M.D., OF WORCESTER,

*Surgeon to the Worcester City Hospital and to the Memorial Hospital.*

MR. BENJAMIN BELL, after a very careful description of injuries to the kidney, their dangers and possible complications, dismisses the question of their surgical treatment with these words: "All that art can with propriety attempt is to prevent the urine from lodging." This was in 1791, and until within a few years art has not attempted to do more. The number of instances in which operative interference has been resorted to for the relief of wounds and injuries of the kidney is still so small as to make each new experience worth recording, and to justify us in considering very briefly when and how such interference may best be employed.

The subject of the following case was a girl twelve years old, who entered my service at the Worcester City Hospital, October 18, 1890. She had always been strong and well, was well nourished, and well developed. It was said that six days before, while stooping over to pick something from the floor, a small pair of shears fell from a height of about seven feet, striking her in the back. They penetrated her clothing and entered the right loin, but, upon raising herself into an erect position, they were dislodged and fell to the floor. Subsequent developments made it altogether probable that they were impelled by a stronger force than that described, but I was never able to obtain any different account of the accident. She was seen soon afterward by Dr. J. H. Kelly of this city, who found a penetrating wound about one inch long, just below the twelfth rib, about an inch and a half to right of the vertebral column. There was no evidence of shock, and but very little external hemorrhage. After cleansing the wound he closed it with a superficial stitch, and primary union had already taken place at the time of her admission to the hospital. On the evening of the accident the urine became very bloody, with numerous clots, one apparently a perfect cast of the ureter. On the following day the urine was clear again, but on the second day the hæmaturia reappeared, and had continued without intermission up to the time when I saw her.

She was then quite anæmic, had a temperature of 102.6°, pulse of 110—complained of pain in the right lumbar region, radiating downward along the course of the right ureter. This pain was somewhat increased upon pressure, but no fullness or increased resistance was discoverable by palpation. The urine was very bloody, with large clots, some resembling casts of the ureter. Microscopic examination of the sediment revealed, beyond the presence of blood, nothing abnormal. The act of micturition was very much increased in frequency, and associated with very marked tenesmus. Sometimes she could not pass water until a clot had been pulled out of the urethra with forceps, or dislodged by irrigation. During the next week her temperature ranged from 100° to 102.5°, while her pulse maintained its strength at 110. She slept poorly, and had no appetite. The twenty-four-hour amount of urine was approximately sixteen ounces, and contained a great deal of bright red blood. The pain was referred chiefly to the

bladder. Up to the 25th of October it had been impossible to note any difference in the loins, but on that morning a semi-fluctuating tumor, the size of a small flattened horse chestnut, could be felt just below and outside the scar of the original wound. The pain in her side was increased, while the urine became perfectly clear. It remained clear for two days, when she had a smart hæmorrhage from the bladder, with coincident disappearance of the tumor in the back. Her pulse had risen to 120, and her temperature ranged from 99° to 102°. Convinced that extravasation into the perinephritic area had already taken place, that the hæmorrhage proceeded from some large branch of the renal artery, and that further delay would only add to the dangers of an operation which must sooner or later become imperative, I decided to operate on the 28th of October, sixteen days after the reception of the injury.

A vertical incision was made on the right side from just below the outer end of the twelfth rib downwards to about three-fourths of an inch above, and just behind the centre of the iliac crest, curving forward from here on the abdomen to a point in the line of the anterior superior spine of the ilium. The quadratus muscle was drawn to one side and the dissection prosecuted through the perinephritic tissue. The latter had become so infiltrated with organized blood-clot that it resembled a cut section of the liver. Retained immediately about the kidney were two or three ounces of dark bloody pus of a decidedly urinous odor. On the posterior surface of the exposed kidney, corresponding in position to the original wound in the skin, was a ragged, incised wound about half an inch long, the edges of which had not united. The ureter was found very much distended, filled with clot, and its walls were so thin that it resembled, and it was at first mistaken for, a large vein. It was cut after being secured by a strong silk ligature. A single silk ligature was then passed around vein and artery together. A transverse incision was made into the kidney to make sure that the vessels had been secured, and it was then removed in two sections, first, the upper one-third, then the lower two-thirds. There was no hæmorrhage—the wound was thoroughly irrigated with bichloride, then with hot water, and a large drainage-tube inserted. It was closed with interrupted silk sutures, and an antiseptic dressing was applied.

At the end of the operation the patient was in a condition of profound shock, with a very rapid fluttering pulse. Upon being placed in bed and surrounded with heaters she rallied quickly, and the pulse became clear and distinct at 164. There was no vomiting, and under the free administration of digitalis and stimulants the pulse had fallen by evening to 140, of good strength. She passed urine involuntarily twice during the night, but slept well; and from that time forward her convalescence was uninterrupted. Her temperature was 102.2° on the night of the operation, and 101.6° on the following night. It never afterward rose above 101°. The amount of urine passed during the first twenty-four hours could not be measured because of the two involuntary discharges, but in the second twenty-four hours it was fourteen ounces, and during the succeeding week it maintained a daily average of fifteen ounces. Two weeks later it had risen to between eighteen and twenty ounces. The stitches were taken out on the fifth day, the tube on the sixth, and on the ninth day she sat up in a wheel-chair. The

<sup>1</sup> Read before the Massachusetts Medical Society, June 10, 1891, and recommended for publication by the Society.

wound was healed except along the track of the drainage-tube, from which there was a slight seropurulent discharge. At the time of the operation she received a severe burn on the sole of the foot, which kept her from walking for a long time, and was the source of much more pain and discomfort to her than the removal of her kidney. On the 9th of December, less than six weeks after the operation, she left the hospital—both wounds healed.

Since her discharge she has grown taller and stouter, has enjoyed excellent health, and attended school regularly. About four weeks ago the track of the tube reopened and one of the silk ligatures came away; the sinus still discharges a very little occasionally, and I presume the other ligature will follow.

Examination of the kidney after removal showed that the blade of the shears had entered its posterior surface near the junction of the lower and middle thirds, midway between the outer and inner borders. Passing downwards and inwards, it had crossed the pelvis of the kidney, severed a large branch of the renal artery, and emerged through the capsule on the opposite side. The wound showed no attempt at healing. The plugging of the ureter by clots caused the extravasation of blood and urine through the wound into the perinephritic cellular tissue, while the urine passed from the bladder came from the uninjured kidney and was perfectly clear. The discharge of the clot allowed the extravasated blood to drain back into the pelvis, and led to the collapse of the tumor as noted on the day before operation. One of the most striking features of this case was the entire absence of shock following so severe an injury to the kidney. To be sure there was no complicating wound of the peritoneum or of other viscera, and the hæmorrhage took place very slowly; still its absence is noteworthy, and suggests, I think, at least as probable, that a simple incision of the kidney will ordinarily produce no constitutional disturbance if the large vessels are carefully avoided.

Accidental wounds and injuries of the kidney are by no means so dangerous as was formerly supposed. Of the eighty cases of gun-shot wounds recorded in the "Surgical History of the War of the Rebellion," all treated expectantly, one-third recovered, and a large majority of the fifty-four fatal cases were complicated by serious injuries to other viscera. The results of subcutaneous rupture and hæmorrhage are even more favorable. In the same history are reported five cases of this nature, with three deaths and two recoveries. To these we may add the 71 cases reported by Maas and the 27 cases of Otis, making a total of 103 cases, with 50 recoveries and 53 deaths. Of the fatal cases, twenty may fairly be attributed to injuries of other organs, leaving the mortality from uncomplicated subcutaneous wounds of the kidney at 33 per cent. Gravit, from a consideration of 108 cases, including most of those just alluded to, places the mortality in uncomplicated cases at 35 per cent. It follows, therefore, that about two-thirds of the uncomplicated cases recover, under the expectant plan of treatment. Punctured and incised wounds speedily become subcutaneous, as in the case just reported, by the closure of the wound in the skin, and present no additional dangers. The natural tendency to recovery in so large a proportion of cases makes the presumption decidedly in favor of a policy of non-interference. More radical measures are to be undertaken only in the presence of clear

and strong indications. It is, of course, difficult to determine when interference is really demanded, and when rest, opiates and cold applications are likely to be sufficient.

A consideration of the fatal cases above mentioned shows that whenever the patient has survived the immediate shock of the accident, death has almost always resulted from hæmorrhage, or from septic infection. If the peritoneum remains intact, the extravasation of blood and urine takes place into the perinephritic and subperitoneal tissues. If the peritoneum is torn, extravasation takes place into the abdominal cavity with, even if the hæmorrhage is inconsiderable, the development of a rapidly fatal septic peritonitis. Of 47 cases in which the cause of death is stated, excluding deaths from primary shock, 23, or 48 per cent., were the result of sepsis, and 15, or 32 per cent., the result of hæmorrhage, that is, 80 per cent. of all cases. Suppression rarely occurs unless both kidneys are injured, or only one exists. Deaths from shock and suppression are unavoidable. Those from hæmorrhage and sepsis are at least, in some measure, controllable. The difficulty is to know when and how.

In general, we may say that surgical interference should be limited to those cases in which one, or both, of these dangers already exists, or may reasonably be expected. Whenever the loss of blood, whether from an external wound, or per urethram, is so great as to threaten the life of the patient, resort must be immediately had to operative interference. A blanched countenance, rapid pulse, and threatened collapse, indicative of internal or concealed hæmorrhage, demand equally prompt action. If the wound is subcutaneous, the only other danger would be from extravasation of urine. If this has taken place into the abdominal cavity, it will be speedily followed by the symptoms of perforative peritonitis—abdominal pain, tenderness, distension with tympanitis, vomiting, and profound prostration. Operation would then always be indicated. If, on the other hand, the peritoneum is not ruptured, and extravasation takes place into the cellular tissue about the kidney, an increasing sense of fulness and tenderness in the lumbar region, with beginning signs of constitutional disturbance, make further delay dangerous and unsurgical. If, instead of being subcutaneous, the wound is of the penetrating sort, we have the same condition of things according as the abdominal cavity is, or is not, opened, and besides the possibility of infective material having been introduced from without. The indications for operative interference just given will still hold good with the following addition. A wound inflicted from the front or side, and injuring the kidney, must in all probability have passed into and through the peritoneal cavity; it ought, therefore, to be thoroughly explored, and the protection of the peritoneal cavity secured. Active interference is also necessary in those cases where urine escapes from a wound inflicted from behind, and not opening the abdominal cavity.

How shall we interfere? There are several methods of procedure: namely, simply a free lumbar incision with drainage; the same incision carried down to, or into, the kidney, with drainage or packing for the relief of hæmorrhage, that is, nephrotomy—dissection in the same region carried still further, and the kidney removed, that is, lumbar nephrectomy—or lastly, laparotomy, exploration of the peritoneal cavity and removal of the kidney through an incision in the mesocolon,

that is, abdominal nephrectomy. As illustrating the results of these methods, allow me to call your attention to the tables derived from Willard's article in the "Transactions of the American Surgical Association," and from Newman's recent work on "Surgical Diseases of the Kidney." There are in all sixteen cases. Of primary operations there are three abdominal nephrectomies, all for gunshot wounds, with one recovery and two deaths; three nephrectomies for knife wounds, all of which recovered, and three for rupture, with two recoveries and one death. — these six through a lumbar incision; two primary nephrotomies, both for rupture, and both successful. There were four secondary lumbar nephrectomies for rupture, with three recoveries and one death, and one similar successful operation for prolapse of the kidney through a lacerated lumbar wound. Of the two deaths from the abdominal operation, one took place on the fifteenth day from gangrene of the intestine, which had been wounded by the bullet, and the other on the fourth day from shock and hæmorrhage, the renal vein and artery having both been severed. The death from primary lumbar nephrectomy was from sepsis, that from the secondary operation was due to shock.

In 1885, Dr. S. W. Gross compiled the statistics from 233 cases of extirpation of the kidney for disease, and found that the mortality by the lumbar incision was about 37 per cent., while that by the abdominal was about 51 per cent. The results obtained from operations for traumatic lesions do not diminish the advantages of the lumbar incision. Except when specially indicated the abdominal should never be the operation of choice. It is to be preferred, I think, whenever the track of the original injury appears to lead through, or into, the peritoneal cavity, and would, therefore, be selected in all cases where the wound was inflicted from the front or side of the body, and whenever there was reason to suspect an extravasation of blood or urine into the peritoneal cavity. Shall the incision be made in the median line or in the linear semilunaris? The kidney must be reached by cutting through the parietal reflexion of the mesocolon, and this lies almost directly under the outer edge of the rectus muscle. Even here the opening in the abdominal wall must be at least four or five inches long — if in the median line it must be much longer, with a consequently increased exposure of the abdominal contents and the additional risk of a more difficult manipulation. Whenever possible the opening in the mesocolon should be closed, and in all cases I would drain from behind. Under all other circumstances in which operative interference is indicated, the kidney is to be reached from the loin. Various incisions have been proposed, and each has its advantage in individual cases. The nature and location of the wound will generally determine the surgeon's choice, as it will the extent of his operation. If there is no escape of urine through the wound, packing with iodoform gauze will control the hæmorrhage, and this, with efficient drainage, will probably be enough. If urine is escaping through the wound, one must decide between primary extirpation and the secondary operation for the relief of the fistula, which will probably result. Other things being equal, secondary extirpation is the more favorable operation. One's judgment as to the ability of the patient to withstand the additional shock of the operation must be weighed against the chances of adhesions being formed, and a more formidable though

secondary operation made necessary. If the kidney is prolapsed through the wound, it may, if uninjured, be replaced, and secured by sutures through the capsule as in nephrorraphy for movable kidney; if injured, it is better to remove it at once.

#### PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

BY HAROLD C. ERNST, M.D.,  
Instructor in Bacteriology at the Harvard Medical School.  
(Continued from No. 4, page 79.)

CASE 32. Boston. Admitted December 9, 1890. Service of Dr. A. L. Mason. Born in Ireland, thirty-five years old, single, stone-mason. Family history negative. Former diseases: fever when a child, and pneumonia in April, 1890, and no enlarged glands at that time. Date of commencement of the disease, October, 1890. Appeared as swelling under the jaws, gradually growing; since then increased, no pain. General health poor. Anæmic; well developed; poor strength and nutrition; appetite good; sleep poor; skin normal; cardiac apex under the nipple; circulation negative; temperature 101.6°; pulse 104; respiration 28; slight dyspnea; alcoholic habit; urine pale, cloudy, 1031, considerable sediment made up of amorphous urates, trace of albumen. Six weeks ago there was pain in the back and calf of the leg, and he had to give up work; lost flesh and strength. One week ago enlarged and sore gums; bad taste in the mouth; the gums bled at night; teeth feel loose, but seem to be sound. Examination showed many large glands from the size of a pea to a large group, soft and distinct, in both cervical triangles; same over the mastoid and under the jaws, and about the clavicle; thyroid glands normal; fullness under the clavicle; bunch of glands in each axilla; epitrochlear glands were large as a pea; left iliac fossa showed some movable glandular tumors an inch or so in diameter; right iliac fossa showed similar but larger masses; the inguinal glands were enlarged; liver and spleen apparently normal.

December 18th. Says he is feeling better; sits up daily with blankets; has no bleeding to-day from the gums.

December 30, 1890. Percussion and respiration of the chest in front, clear; in the back, slight dullness near the spine in the right lower back, with bronchovesicular quality to the respiration, and occasional, fine, moist râles; on the left, respiration slightly broncho-vesicular along the region of the spine. Weaker in the last few days.

January 29, 1891. Examination of the lungs by Dr. Stickney. Breathing showed higher pitch over the upper front than below. The right apex shows an approach to tubular breathing. Expiration slightly higher pitch and prolonged, very few râles on long breath after cough; doubtful modification in the percussion note; back showed no râles; respiration less distinct at bases than at top; voice-sounds more distinct at the top; heart regular; no cough; no expectoration; some night sweats, but none at present; feels well, and is not losing flesh or strength. Glands in the axilla unchanged; in groin, rather harder and larger.

February 2d. Urine normal, acid, 1029, no albumen, few uric acid crystals.

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1891.

February 4th. Dose, .0012 gm.

No special symptoms. On the 3d, bacilli in the sputum, 0; bacilli in discharge from the neck, 0.

February 6th. Dose, .0034 gm.

Headache in the afternoon; appetite slightly diminished; sputum, thin, watery, claret color, the color probably coming from the gums.

February 8th. Increased headache; dyspnoea; poor appetite and sleep; no increase of cough or sputum. On the 7th of February, examination of the sputum for bacilli was negative.

February 9th. Urine normal, acid, 1033, no albumen, many urates.

February 10th. Dose, .0024 gm.

Headache and general malaise; poor appetite and sleep; no especial change in the glands; surrounding infiltration diminished. On the 8th, bacilli in the sputum, 0.

February 11th. Gradual increase of cough; bacilli in the sputum, No. 1; no discharge from the neck, and no redness.

February 12th. Dose, .0048 gm.; 16th, .005 gm.; 20th, .005 gm.; 24th, .005 gm.; 26th, .0052 gm.

March 2d. Dose, .006 gm.

March 6th. Dose, .0072 gm. Abdomen distended.

March 10th. Dose, .0084 gm.

March 14th. Dose, .0072 gm. Glands in the neck diminished in size; abdomen less distended; is more comfortable.

March 18th. Hemoglobin, 50 per cent.

March 21st. Was doing well until yesterday, when the temperature suddenly rose to 105°, and has remained there; much dyspnoea; rapid and weak pulse; lips cyanotic. Examination by Dr. Rotch shows dullness over the right lower back, with numerous fine, moist rales; increased vocal resonance and fremitus.

March 23d. Blood shows no bacilli. Is much worse; pulse rapid, small; face of ashen-gray; is conscious; respiration rapid and superficial; orthopnoea; unable to talk. Died suddenly.

Autopsy, March 24th, by Dr. Gannett, twenty-three hours after death, at 9 A. M. Body of medium size, well developed, somewhat emaciated. Marked enlargement of neck, due to the presence of a large number of nodules, varying in size from a pea to a walnut. These were of a moderate density, showing on section a reddish color, somewhat translucent and succulent. There was an extended development of similar nodules under the clavicles and into both axillae, the largest of them being the size of a big plum. The under surface of the sternum showed an extended development of similar nodules; following down the trachea was also an extensive development of the same. The heart showed nothing abnormal. The lower portion of the left lung was darker and firmer than usual; on section, the surface moist, yielding on pressure considerable thin aerated fluid. The right pleural cavity contained by estimate two litres of clear serous fluid; the pleural surfaces covered with abundant fibrinous false membrane. The lower portion of the lower lobe was solidified, showing on section a reddish-gray, granular surface. The remaining portions of this lung were normal. The spleen measured twenty-one by six and one-half centimetres, and weighed twenty-nine grammes; section showed appearance of chronic hyperplasia. The peritoneal cavity was occupied by a mass of nodules like the already described, of mesenteric and sub-peritoneal origin, which formed altogether a mass

the size of a large pumpkin. They ranged in size from a pea to an apple, the largest being markedly hyperaemic. There was also considerable development of similar nodules under Poupart's ligament. None of the nodules described, however, show any evidence of necrosis or degenerative change. The kidneys and liver were normal. The mucous membrane of the lower portion of the ilium showed elevated, flattened, opaque gray nodules, and the solitary follicles, here, and in the large intestine, were considerably enlarged. Bone marrow was of red and gelatinous consistency.

*Diagnosis.*—General: Pseudo-leucæmia. Special: Malignant lymphomatous nodules of the neck, axillæ, mediastinum, vertebral region, peritoneum in general; chronic hyperplasia of the spleen. Acute fibrinous pleurisy; acute fibrinous pneumonia.

A puzzling case. Temperature reaction. Bacilli in sputum obee. No apparent effect from the treatment. No signs of tuberculosis upon autopsy.

CASE 33. Philadelphia. Admitted February 9, 1891. Service of Dr. E. H. Bradford. Nativity American, seven years old. Disease commenced in January, 1890, splint applied in July, 1890. Heart and circulation negative; chest negative; abdomen negative. Entered with a sensitive hip; no motion. Induration above the upper part of the thigh; no evidence of abscess.

February 14th. The condition of the leg is normal under extension. With extension omitted, there is strong tendency to abduction, flexion and inversion. Marked muscular spasms on attempted passive motion. Length of the right leg, twenty-three and one-half inches; left, twenty-three and one-half inches. Circumference of the right thigh, eight and three-quarters inches; left, ten inches. Circumference of the right calf, seven inches; left, eight inches. Hard, enlarged glands in the inguinal region.

February 20th. Dose, .0002 gm.

April 8th. Dose, .006 gm. Weight, 16.2 kilos. Treatment omitted temporarily.

*Summary.*—Number of injections, 22; amount used, 76.1 mg.; highest dose, 6 mg.; highest temperature, 105°, after the sixteenth injection of 4.8 mg. Discharged, not relieved. No change that could be attributed to the treatment. General condition is, however, better.

CASE 34. Tiverton, R. I. Admitted November 19, 1890. Service of Dr. E. H. Bradford. Born in Rhode Island, eleven years old, of Irish and English parentage. Trouble began in January, 1889, after a fall on the right side, with pain at night, and lameness. Entered with hip flexed at 60°; no abduction nor adduction; slight area of fluctuation behind the trochanter; night cries.

February 11, 1891. Condition poor. Moderate discharge from the sinus in the gluteal region. Permanent adduction five degrees. No flexion; no motion possible in flexion, abduction or rotation. Night cries occasional and faint. Chest and abdomen negative.

February 20th. Dose, .0003 gm.

April 8th. Dose, .008 gm. Treatment omitted temporarily.

*Summary.*—Number of injections, 23; amount used, 114.4 mg.; highest dose, 8.4 mg.; highest temperature, 101.1°, after the fourth injection of 1.5 mg. Discharged, relieved. General condition improved. Night cries gone. Discharge from the hip less.

These cases seem to be classified as follows :

(1) Not relieved, twelve, — including Cases 13, 16, 17, 19, 21, 22, 24, 25, 29, 30, 31, 33.

Of these, Case 13 (lupus of the face) showed a very great and rapid improvement, at least apparently, at first, and then stopped.

Case 19 (empyema, with drainage-tube found in the pleural cavity) might readily be thrown out entirely, except that this is a record of the cases that have been under treatment, not a selected and revised edition. It certainly cannot be taken as proving anything for or against the material, although after surgical interference, the patient is very much better, and the wound is almost, if not entirely, healed.

Case 21 (suppuration of the toe, with slight pulmonary signs, but no bacilli) is reported better, as regards the pulmonary signs, by Dr. Mason.

Case 24 showed improvement at first, but was not better at the time last seen, (lesion of the back of the hand).

Case 25 (tuberculosis of the tongue, with pulmonary lesion at the apex) showed a marked improvement at first; but this improvement was arrested, and the disease is now further advanced than at the beginning of treatment.

Case 29 (disease of the wrist) seemed to present a peculiar appearance upon opening the wrist, inasmuch as there was a complete absence of anything that would account for the keeping open of the sinus there. The wound healed kindly after the removal of the thickened membrane of the sinus.

(2) Relieved, six, — including Cases 14, 15, 23, 26, 27, 34.

Case 14 (lupus of the face and thigh) was classed as relieved because of the marked diminution of the infiltration and thickening of the thigh; of the equally marked and similar change in the condition of the face; and the improvement in the general condition of the patient. All the ulcerative patches were not closed, and at the date of the last observation (May 3d), there seemed to be indications of a renewal of the active process, but, of course, the best that can be done in a report like the present, is to state the condition at the time that the report is made up.

Case 15 (tumor in Douglas's pouch — no real evidence of tuberculosis) showed a very great and marked improvement in general condition, up to the time of the attack of measles. There was a constant and gradual increase in weight of ten pounds, a diminution of the local distressing symptoms; and this, following the contrary condition of affairs, and beginning with the injections.

Case 23 (enlarged and suppurating cervical glands) showed sudden enlargement of one gland, with discharge following the treatment; followed by a cessation of any reaction, local or general; by the closing of the sinus; the diminution of size of the gland, and cessation of its activity; together with a marked increase in weight.

Case 26 (disease of the ankle — bacilli found in the discharge) improved afterwards enough to have motion in the joint; no bacilli were found afterwards in the discharge from the ankle; and there was a change for the better in the general condition.

Case 27 (hip disease) showed a marked improvement in the general condition; a diminution of the discharge from the hip, and a diminution in the subjective symptoms.

Case 34 (hip disease) general condition improved; discharge from the hip less; subjective symptoms less.

(3) Much relieved, two, — Cases 20 and 28.

Case 20 (pseudo-leucæmia) after leaving hospital, suffered from a sharp febrile attack, accompanied with great enlargement of the glands (situated principally in the cervical region), lasting for three or four days; followed by a rapid diminution in size of the glands and a marked improvement in the general condition, that has held up to within a week (more than six weeks after the cessation of treatment). The case is an exceedingly puzzling one. The patient certainly felt himself, that a most extraordinary change for the better had taken place in his condition. The enlarged glands were, at the time of last inspection, remarkably diminished in size.

Case 28 (hip-disease, ulceration of the cornea, enlarged cervical glands) showed a great gain in general condition; the ulceration of the cornea is arrested; the cervical glands are normal in size; the discharge from the hip is much less; and the patient is about on crutches.

(4) Died, two, — including Cases 18 and 32.

Case 18 was desperate from the start. The patient had been running down as rapidly as possible for some time before entrance; had been operated upon four or five times for the removal of the affected glands; had pulmonary lesions in addition to amyloid kidneys, spleen, and probably liver. She died of exhaustion, about two weeks after removal from the hospital, and four weeks after the last injection. At present, no considerations of feeling or friendship should permit the treatment of such a case.

Case 32 (pseudo-leucæmia) is one of the most interesting cases that have come under observation. There was marked temperature reaction during the treatment. Bacilli were found in the sputum once (on February 11th); and yet at the autopsy there was no sign of tuberculosis anywhere — in the gross appearances; nor have any certain microscopic signs yet been found, although the examination has not been thoroughly completed. At first, the case was supposed to be as perfect a one as could have been selected against the value of tuberculin in diagnosis (or indeed anything else); but the fact of the discovery of the bacilli in the sputum puts a different face upon the matter, and judgment in regard to it must be temporarily suspended. The death in this case was distinctly due to an intercurrent attack of pleurisy and pneumonia, and not to the injections.

In this series, as in the former one, there are no cures to report; and, equally as in the preceding series, the judgment passed upon each case is necessarily only a temporary one.

The next class into which I have divided the cases, is that of those treated for diagnosis. They were all treated at a time when more reliance was placed upon the use of tuberculin for diagnostic purposes, than is at present the case. There are eight of these, as follows:

#### SECTION III.

##### TREATED FOR DIAGNOSIS. — CASES XXXV—XLII.

CASE 35. Providence. Admitted November 29, 1890. Service of Dr. C. B. Porter. Born in Massachusetts, twenty-one years of age, single, machinist.

Family history negative. Had measles; typhoid fever two years ago. The disease began in August, 1890, with pain below the right nipple, and a small tumor made its appearance. General health good; appearance anæmic; fair strength and nutrition; good appetite; fair sleep; skin pale; slight pain, at times sharp in the side and back; urine normal; abdomen negative.

Examination shows a well-developed and nourished man, with a tumor about three-quarters of an inch in diameter on the sixth rib, near the junction of costal cartilage; hard, non-fluctuating, not red or tender.

January 16, 1891. Physical examination by Dr. Tarbell negative. Tumor conical, with a base two and one-half inches in diameter, and a height of one and three-quarters inches.

January 17th. Urine normal, acid, 1014, no albumen, many amorphous urates.

January 18th. Dose, .002 gm. Headache; increased pain in the back and lumbar region; a marked fever, lasting for three days.

January 22d. No cough; no expectoration.

January 23d. Dose, .0024 gm. Pain increased in the lower back. Examination by Dr. Tarbell negative, except a very slight harsh respiration in the left back.

January 27th. Dose, .003 gm. General malaise; poor appetite; poor sleep; vomiting; pain increased in the lower back. The tumor has enlarged to a marked degree. Discharged from further treatment at his own request. Went home to await further changes.

*Summary.*—Number of injections, 3; amount used, 7.4 mg.; highest dose, 3 mg.; highest temperature, 102.4°, after the third injection of three milligrammes on the third day after the injection. Discharged, not relieved. Whether this patient was made worse or not by the treatment is an open question. The same febrile attack and disorders of digestion had occurred before.

CASE 36. Boston. Admitted February 12, 1891. Service of Dr. Bolles. Born in Medina, twenty-three years old, single, barber. Family history good. Denies venereal disease. Drinks slightly to excess. Smokes a great deal. Disease began thirteen months ago, with pain on the internal apex of the left tibia. In appearance, well developed; good strength and nutrition; fair appetite; good sleep; heart and circulation negative; breathing regular but rapid; urine (on February 17th) normal, acid, 1030, no albumen. The left leg shows a regular swelling, rather larger than an egg, on the inside of and just below the knee-joint, at the level of the head of the tibia; tender in all parts, non-fluctuating, apparently solid, not red, skin not broken.

February 18th. Dose, .0012 gm., followed by no reaction.

April 13th. Physical examination showed the right knee back dull; diminished respiration; old pleuritic friction; subcrepitant rales.

*Summary.*—Number of injections, 3; amount injected, 9.6 mg.; highest dose, 6 mg.; highest temperature, 100.4°, after the third injection of six milligrammes. Discharged, not relieved. Specific disease suspected.

CASE 37. Boston. Admitted January 2, 1891. Service of Dr. Warren. Born in Massachusetts, twenty-four years old, single. Good family history. Disease

commenced three years ago with ulceration in the nose and then on the lip. General health fair; menses regular; is anæmic; fair strength and nutrition; good appetite and sleep.

February 3d. Urine pale, acid, 1010, no albumen, abdomen negative. When twelve years old had diphtheria, and has been deaf ever since. The nose is entirely destroyed, and the bones of the septum and the turbinates are entirely gone. The necrosis extends to the base of the skull, and there is ulceration as far as the pharynx.

February 9th. Dose, .0006 gm. Had increased pain in the pharynx; pain was very unusual.

February 11th. Dose, .0018 gm. No change of any kind.

February 13th. Dose, .006 gm. Pain increased in the forehead. Any pain at all is extremely unusual.

February 15th. Dose, .0096 gm. Slight pain. The patient was given Shaw's Specific and sent home to take iodide of potash, and report from time to time.

*Summary.*—Number of injections, 4; amount used, 18 mg.; no temperature record kept.

April 25th. Improving rapidly under specific treatment.

CASE 38. Topsfield. Admitted January 29, 1891. Service of Dr. J. C. Warren. Born in Nova Scotia, about forty-five years old, married, housewife. Disease has lasted for sixteen years after the birth of her last child, beginning with varicose veins. Menstruation regular. Has had at least two children. Good appearance and strength; fair nutrition; good appetite and sleep; skin dusky; heart and circulation negative; no chills, fever or night sweats. Fourteen years ago, dark purple area appeared under the skin over the patella, which broke down, leaving an ulcer. Similar ulcerations appeared later, which healed, leaving a thick indurated red skin covering an area of about six inches, in some parts of which the skin has broken down. Outside of this red indurated area is a deep ulcer, with a slough in the centre. Above this is a red purple area, thick and distinctly indurated; and above this a dark-purple area less indurated. The skin of the whole leg about the knee is thickened and indurated, suggesting elephantiasis. No glands are to be felt. The knee is not painful, and the patient considers herself a well woman except the local trouble. Has had many physicians, and taken much medicine.

January 15th. Dose, .0012 gm. Bacilli in the discharge on the 29th, 0. Slight reddening of the diseased area.

February 3d. Dose, .0024 gm. Pain increased in knee. Urine normal, acid, 1032, no albumen or sugar, urates increased. Pain partly due to a dry dressing.

February 5th. Dose, .0048 gm. Headache; increased pain and swelling of the knee; bacilli from the discharge, No. 0. Could not walk as well after the injection.

February 7th. Dose, .006 gm. General discomfort.

February 9th. Dose, .006 gm. A piece punched out, and sent to Dr. Whitney, who makes the following report: "A general round-cell infiltration, with here and there enlarged nerves. In one place an area of necrosis. Syphilis?"

February 11th. Dose, .0072 gm.; 13th, .010 gm.; 15th, .014 gm. No reaction after any of them. The diagnosis was negative and the patient discharged.

*Summary.*—Number of injections, 8; amount used, 52 mg.; highest dose, 14.4 mg.; highest temperature, 101.8°, after the fourth injection of six milligrammes. Discharged, not relieved. Specific disease suspected.

CASE 39. Charlestown. Admitted December 30, 1890. Service of Dr. J. C. Warren. Born in Maine, fifty years old, married, mechanic. Disease began in October, 1890. General health fair; poor appearance; fair strength, nutrition and appetite; good sleep; temperature, 97.8°; pulse 90; pain in elbow. The left hand and arm are swollen and oedematous; the elbow swollen, red, and painful on attempted movement. The probe grates on dead bone on the posterior surface of the olecranon.

January 1, 1891. Dose, .001 gm. General condition, appetite, and sleep poor; pain in the arm and elbow and abdomen, probably due to indigestion.

January 5th. Dose, .002 gm. Pain increased in the arm.

January 7th. Dose, .002 gm. Discharge from the arm slightly increased.

January 9th. Dose, .0025 gm. Pain in back and elbow. Subjective symptoms doubtful.

January 30th. Wound reduced to a small sinus, practically closed. Discharged (with a splint), to go to out-patient department.

February 28th. The wound is completely closed; power returning to the arm muscles; motion of the joint completely returned; has gained in health and strength.

*Summary.*—Number of injections, 11; amount of material used, 36.3 mg.; largest dose, 8 mg.; highest temperature, 100.8°, after the sixth injection of 2.2 mg. Discharged, much relieved. It can hardly be said that the treatment accomplished this result, although the patient himself thought so.

CASE 40. Orange. Admitted December 30, 1890. Service of Dr. C. B. Porter. Born in Massachusetts, twenty-nine years of age, married, housewife. No other diseases up to the time of injury. July, 1890, fell. General health that of a nervous, hysterical woman. Well developed; fair strength; good nutrition, appetite and sleep.

Examination showed the left elbow somewhat swollen; all motions possible were apparently painful; no evidence of old fracture. A fluctuating area over the head of the radius was about one inch in diameter. Ordered a phenyl poultice every four hours.

January 3, 1891. Dose, .0008 gm. No general reaction; no pain; no discomfort at seat of lesion.

January 5th. Dose, .0018 gm. No general or local reaction.

January 6th. Able to comb her hair this morning for the first time since the beginning of the trouble. Don't feel sick. Desires to go home, and decides to have no more treatment.

January 8th. Swelling in the elbow very much diminished. Free motion without pain. Discharged.

*Summary.*—Number of injections, 2; amount used, 2.6 mg.; highest dose, 1.8 mg.; no rise in temperature. Discharged, much relieved (but not by the treatment).

CASE 41. East Boston. Date of admission November 29, 1890. Service of Drs. Gavin and Bradford. Born in Canada, seventeen years of age, school-girl. Good family history. Typhoid fever three or four years ago. Disease commenced October 30, 1890, following typhoid. Swelling about the hip-joint, and

half-way down the outer and posterior side. Thought to be thrombosis following typhoid.

January 4, 1891. Dose, .0006 gm. Slight headache.

January 8th. Dose, .0006 gm.

January 12th. Dose, .0012 gm. Slight headache; nausea in the afternoon.

January 13th. No swelling of hip, or increased tenderness, has been noticed. The reactions not having been satisfactory, the treatment was given up. General condition has been improving; gaining in flesh (January 20th).

February 2d. General condition excellent.

April 3th. Still in hospital.

*Summary.*—Number of injections, 3; amount used, 2.4 mg.; highest dose, 1.2 mg.; highest temperature, 101°, after the third injection of 1.2 mg. Discharged, not relieved. No reaction followed injections.

CASE 42. South Boston. Admitted January 6, 1891. Service of Dr. E. H. Bradford. Born in Scotland, fourteen years old, school-boy. Disease seven years old, resulting from a blow. Fair nutrition; urine high, acid, 1029, no albumen. The left leg, just below the crest of the tibia, showed a small superficial granulating area, from which there is a slight discharge; some thickening of bone felt about this area, but no sinus.

January 12th. Dose, .001 gm. Headache; slight nausea.

January 14th. Dose, .0016 gm.

January 16th. Dose, .003 gm. General condition good.

January 14th. Discharge from the granulated surface increased, and the surface was healed, with no pain. As the patient was showing almost no reaction and the wound had healed, treatment was omitted. Discharged, relieved.

*Summary.*—Number of injections, 3; amount used, 5.5 mg.; highest dose, 3 mg.; highest temperature, 100°, after the second injection of 1.6 mg. Discharged, not relieved by treatment, but much better.

Case 35 (a tumor on rib) showed a marked febrile reaction following the injection and lasting for several days. The same sort of febrile attack had, however, occurred before the treatment began.

In Case 36 (disease of the tibia), Case 37 (disease of the face), and Case 38 (disease of the knee), specific disease was suspected,—partially confirmed in Case 37 by improvement under iodide, and in Case 38 by the microscopic examination.

Cases 39 and 40 (affection of the elbow) both showed marked improvement after the injections; but in neither case could the treatment be held responsible for this improvement, although both patients felt that it was. In Case 39 there was actual improvement after surgical interference; and Case 40 was an apparent instance of extremely rapid and effective "mind-cure" in an hysterical woman.

Cases 41 (disease of the hip) and 42 (disease of the tibia) showed no reaction, general or local; and the treatment was dropped for that reason, although at present the indications seem to be that results might have been obtained if it had been carried further.

(To be continued.)

PROF. OSKAR HERTWIG, of Berlin, is about to publish an essay on "The Physiological Basis of the Effects of Tuberculin."

## Medical Progress.

### RECENT PROGRESS IN THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M. D.

(Continued from No. 4, p. 83.)

#### TREATMENT OF DYSENTERY.<sup>11</sup>

Dr. H. A. FAIRBAIRN calls attention again to the advantages of irrigation of the large intestine and the thorough flushing of its contents. In the early stages the walls of the intestines are not liable to be weakened by deep ulcerations. The amount of fluid which may be safely used is three or four pints, since the capacity of the large intestine, as a rule, is about six pints. The temperature of the water, which should have been boiled or distilled, should be about 100° or 105° F., except, possibly, in the first or second administration when quite a low temperature appears of benefit. The patients are confined to bed, are deprived as much as possible of food, except whiskey well diluted. Peptonized milk in very small quantities, not more than a quart in twenty-four hours. If the patient will take no food for forty-eight hours it is a great advantage.

The liquid preparations of beef, with their concentrated salts are apt to be irritating. Eggs, scraped beef, or, when these are objected to, steak, roast and chop, with bread, make up the dietary. A cathartic may be administered at the beginning of the case. If there be nausea, calomel in small and frequently-repeated doses is the drug chosen, otherwise sulphate of magnesium. Salol is then ordered, and opium in some form if the pain demands. Naphthalin and corrosive sublimate may also be employed.

#### EPSOM SALTS IN THE TREATMENT OF ACUTE DYSENTERY.<sup>12</sup>

Powdered ipecac is the remedy which is most frequently used in the treatment of acute dysentery, and in India large doses of it are considered the best method for attacking the disease.

There are, however, objections to be used against the administration of large doses of ipecac in this disease. Its influence is depressing, and this action is promoted by the nausea and vomiting, and, further, the vomiting may become uncontrollable. The disease is one which is accompanied by much nervous depression, and it is important not to increase.

After observing a number of cases in which there were marked depressing effects from ipecacuanha, Dr. A. W. Leahy began treating cases of acute dysentery with a saturated solution of sulphate of magnesium, following a recommendation of Bartholow's, who regards the administration of sulphate of magnesium as the most efficient treatment of this disease, particularly in the acute stage.

Dr. Leahy gives a table of nearly one hundred cases treated at Hyderabad among the poorer class of patients, the vitality of many of whom was at an exceedingly low ebb when they came under treatment. Out of ninety-five, three died; two out of these three cases were stated to have been in a moribund condition at the time of their admission to the hospital. It appears that, on an average, two days' treatment with Epsom salts is required to produce disappearance of

dysenteric symptoms. The treatment subsequent to the production of this condition consists of an astringent mixture, with opium. The method of administration is to take a sufficient quantity of sulphate of magnesium to saturate seven fluid ounces of water, and to this saturated solution add one ounce of diluted sulphuric acid. The dose of this is a tablespoonful every hour or two in a wineglassful of water until it operates. Sulphate of morphia may be combined with it, or starch enemata with laudanum may be employed.

Dr. Leahy claims that in the earliest stages of dysentery this saturated solution of Epsom salts acts like a charm; fever, if present, disappears; mucus and blood are wanting in the stools, which become copious, feculent, and bilious; the tenesmus ceases; the patient's anxiety diminishes; the skin acts well, and sleep follows the administration of the first few doses.

It is especially in acute cases that the sulphate of magnesium is so valuable; the more chronic the disease becomes, the less apparent are the advantages of this method of treatment. Dr. Leahy has ordinarily given a drachm of this saturated solution with ten drops of dilute sulphuric acid every hour or two until its effects become evidenced in the feculent character of the stools and their freedom from blood and mucus, or until the temperature has fallen, and the pain and tenesmus have ceased. When the stools have become normal in color and appearance, and the patient only passes two or three in the twenty-four hours, an ordinary astringent mixture of acid with laudanum or tincture of Indian hemp, or a pill containing extract of opium, is usually all that is necessary to complete the cure. It is, of course, imperative to diet the patient with great care.

This treatment Dr. Leahy compares with that by ipecacuanha as follows: It has no depressing action on the system, it neither produces nausea nor vomiting; it quiets and soothes the patient.

In twenty-seven cases of acute dysentery among Europeans all were successfully cured.

It is peculiarly in acute dysentery that the saturated solution of sulphate of magnesium will yield such excellent results. The more chronic the case the less likely is the remedy to prove of value.

#### SULPHONAL IN DIABETES.<sup>13</sup>

Dr. V. Casarelli has used sulphonal in diabetes with the following results: Sulphonal exerts a favorable influence upon the chief symptoms of diabetes, diminishing the quantity of sugar, also the polyuria and polydipsia. These results are obtained in a moderate degree by a dose of 15 to 30 grains *pro die*. They are more marked with a dose of 45 grains, which may be given for several days; 30 grains is well borne for a longer time, 15 grains creates no disturbance at first, but if persisted in for a time produces dizziness and excessive somnolence, which disappear upon the reduction of the dose.

The favorable effects of sulphonal are as evident with a mixed diet as with a strict meat diet; in the latter sugar was found in great quantity in the urine after sulphonal had been suspended.

In the same cases antipyrine was tried before sulphonal, but the effect produced by antipyrine was less marked than that by sulphonal.

CHLORATE OF POTASSIUM POISONING.<sup>14</sup>

Dr. Lauderer, assistant in the medical clinic of Professor Leube, Würzburg, reports a fatal case of poisoning in a young man, eighteen years old, after taking an ounce of chlorate of potassium. It was intended to be used as a gargle, but he dissolved the salt in a glass of warm water, and drank the whole of it in two portions within half an hour.

The first symptoms, which came on shortly after the ingestion of the drug, were weakness, thirst, and dizziness; the more serious symptoms, the result of the action of the salt upon the blood, were acute anemia, dyspnea, cyanosis, continued vomiting, pain in the hypochondrium and near the umbilicus, icterus; liver and spleen both enlarged.

The amount of urine was very small, three and a quarter ounces in seven days, and contained little or no chlorate of potassium. It contained much albumen and sediment. The patient died on the sixth day without convulsions or other uramic symptoms.

The autopsy, made by Professor Rindfleisch, gave the following: (Edema et hypostasis pulmonum, nephritis acuta cum infarctu hæmoglobinurico ex intoxicatione kali chlorici. Gastritis acuta, erosiones ventriculi. Enteritis et colitis acuta follicularis cum erosionibus in jejunum.

The case was under observation from the beginning, and was studied carefully, and the author gives much detail at length, besides some discussion of the observations of others. His conclusion is that chlorate of potassium should be excluded from our list of remedies, and certainly never used for children.

TREATMENT OF OBSTRUCTIONS OF THE BOWELS BY LARGE DOSES OF OLIVE OIL.<sup>15</sup>

Dr. E. W. Mitchell, of Cincinnati, reports two cases of successful treatment of obstruction by means of olive oil, this method of treatment being the result of a suggestion of Professor Langdon. One of the patients, a man, fifty-three years old, had had an operation for strangulated inguinal hernia on the left side, twenty months previously. When seen by his present trouble he had not been well for a day, there had been severe colicky pains and vomiting after each attempt to take food. Enemata were given on this and the following day, with little result. Morphine was given, and large enemata through a rectal tube, introduced as far as possible, produced no effect. Almost two quarts of dirty fluid was withdrawn through a stomach-tube. Two ounces of sweet oil were ordered to be taken every hour. Tympanites during the afternoon and early evening had rapidly increased. There was much prostration, no nourishment having been retained. During the night, half a pint of oil was taken. In the morning there was less prostration; there had been a small fluid passage. An enema now administered through a rectal tube (English gum catheter, No. 16) returned slightly discolored, and containing a trace of oil. There was a recurrence of vomiting, but the oil was continued. About noon the bowels began to move, and several fluid stools were passed during the following night. On the next day the stools became formed and contained pus in small quantities. The case was probably one of fecal impaction — there was no evidence of typhilitis or perityphilitis.

The second case was that of a young man, twenty-

two years old. The bowels had not moved for forty-eight hours, and he had been suffering from tormina and vomiting. Large doses of cathartics had already been taken. Thorough examination failed to find any evidence as to the point of obstruction; the hernial openings were clear, there was no point of tenderness, no tumor, the abdomen was quite tympanitic. He was treated by sulphate of magnesia, repeated clysters through a rectal tube introduced as far as possible into the bowel, and sufficient morphine to control extreme pain. This treatment was continued for two days with no benefit, the tympanites increasing, vomiting became stercoraceous, and the patient much prostrated. The administration of sweet oil was then begun; a pint was taken within a few hours, most of which was retained, although he had before been vomiting everything. Three hours after beginning the oil the bowels began to move, and a good recovery ensued.

Dr. Langdon mentioned in the same journal eight cases where relief had been obtained from large doses of olive oil.

TREATMENT OF INTERNAL HÆMORRHAGE.<sup>16</sup>

Dr. John Ferguson has given a very good outline of some of the ways in which a practitioner may render aid to his patients in this emergency.

Among the remote ways of treating internal hæmorrhage are, lowering the blood-pressure and changing the character of the blood itself. It is very apparent that the amount of blood that will flow through the rent in wall of any vessel must be greatly influenced by the total amount of blood in the system and the amount of pressure upon the vessel from within. This being the case, the first step to take in dealing with a hæmorrhage is to cut off the supply of liquids. In this way the amount of blood is kept down, while it becomes thicker and better fitted for forming a good firm clot in the torn or ruptured vessel. Another step in the same direction is to reduce the volume of blood by actively eliminating water from the system. The hypodermic injection of pilocarpine rapidly unloads the body of water and inspissates the blood left behind, lessening thereby the freeness of the flow. This would not, however, be suitable in cases of pulmonary bleeding. Other diaphoretics might be selected, according to the judgment of the physician.

Those purgatives that produce copious watery stools, and, at the same time, are not irritating or depressing, must be placed on the list of agents we may use for the relief of the sufferer entrusted to our charge. Of these purgatives there is none so good as Epsom salts. When given in saturated solution, without water, in free doses and often repeated, very free watery evacuations are produced, the amount of fluid in the vascular system is speedily lessened, and the hæmorrhage to this extent controlled. By maintaining this action for some time, the ruptured vessel has time to heal, because the pressure is largely taken off and it is put into the condition of rest. In addition to this, the blood is thickened. In some cases of cholera — sporadic or epidemic — when rice-water stools have been very abundant, and the blood becomes so reduced in volume and so inspissated as not to flow from a wound made in a large vein. In the event of hæmorrhage due to ulceration in typhoid fever, this plan could not be had recourse to, though it might be used with advantage in the bleeding from a gastric ulcer. In the hæmorrhage,

<sup>14</sup> Deutsches Archiv. f. Klinische Medicin.

<sup>15</sup> Cincinnati Lancet-Clinic, No. 3, 1891.

<sup>16</sup> New York Medical Record, December 1, 1890.

often so free from soft and rapidly-growing uterine fibroid, it is especially useful if continued long enough — say for months.

In severe post-partum hæmorrhage, the medical attendant may try ergotin hypodermically, or hot vaginal or rectal injections, but this may fail. It is a belief, not yet quite dead, that the uterine sinuses are closed by clots. This is quite erroneous. The uterine vessels and sinuses are interlaced by muscular fibres, and it is the contraction of these that arrests the hæmorrhage. This muscular tissue, as it were, ligates the vessels that would bleed, and, so long as the contraction is good, there is no danger. For the maintenance of the tonic action of the muscular tissue in the uterus the application of heat to the lumbar portion of the spine has been found very useful. It stimulates this portion of the nervous system by bringing more blood to it. There is a great influx of nerve-energy to the uterus, and contraction is brought about. It is true that the uterus seems to be very independent of the spinal cord, and labor may take place in a paraplegia. This does not, however, invalidate the fact that heat — applied to the spine by a sponge dipped in hot water — does much good in the way of rousing the uterus into action. But when all things fail, as a last resort you may tampon the uterus and vagina thoroughly with iodoform gauze, or, if this is not at hand, some cloths to which glycerin is added. The bleeding is soon arrested, the uterus begins to contract, tone in the walls is secured, and one can feel at ease that the patient is out of all immediate danger.

In capital operations, such as the removal of large and vascular tumors from the neck, the female breast, etc., the plan is to simply tie the bands around the legs and arms close up to the body. This arrests the return of blood to the body, while the flow of blood into the limbs still goes on. By this means a very large amount of blood in the body is rapidly collected into the four extremities and the pressure is taken off the central vessels. This method gives time for the use of other means.

#### BORIC ACID IN CONSTIPATION.<sup>17</sup>

Herr Flatau has suggested to the Medical Society of Berlin the use of boric acid in chronic constipation. In cases where the lower part of the rectum protrudes through the anus, and remains visible after powerful contractions of the levator ani and sphincters, the quantity of forty-five grains of boric acid is either dusted or rubbed on the mucous membrane in sight. In cases in which the mucous membrane is not visible it must be insufflated. It is important that the medical attendant should carry out the procedure himself, at any rate at the commencement. The patient should then keep quiet for a time. In from an hour to three hours peristaltic action will be observed in the colon. He has never seen a failure from this method of treatment, nor has he seen a case where the patient got so accustomed to it that it ceased to be effective. On the contrary, if carried out systematically daily, permanent improvement in time takes place, and normal peristalsis is secured.

#### HÆMORRHOIDS.<sup>18</sup>

Dr. W. R. Thomas is very confident that the majority of cases of hæmorrhoids we meet with are entirely preventable, and that many of those which are far

advanced can be cured by medical treatment alone, but it is necessary when treating them to give due consideration to all the causes and treat each one. Among the factors which have to do with the production of hæmorrhoids, and each one of which should be considered in the treatment, there are many: The valveless condition of the portal veins; gravitation; obstruction owing to hepatic, cardiac, or pulmonary disease; sedentary habits; excessive eating and drinking; excessive obesity; and a too frequent use of purgatives.

For successful treatment, the patient should have a daily movement of the bowels regularly. Sponging the anus and surrounding parts with soap and cold water, is a very efficient application, thus removing acrid fluids which, during the ensuing day, would irritate the skin. A large proportion of vegetable diet, and a smaller proportion of meat. Cases of hæmorrhoids with constipation may sometimes be cured by attention to this alone. Sufficient exercise is of much importance. Some patients may obtain relief from a daily injection of as much water as can be retained for four or five minutes with comfort. Lukewarm water may be recommended at first, but as soon as the patient can bear it, cold may be ordered. Those who suffer from hæmorrhoids should, if possible, give up taking stimulants entirely.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, Monday, April 13, 1891, the President, Dr. FREDERICK I. KNIGHT, in the chair.

Dr. H. H. A. BEACH read a paper on,

#### COMPRESSION IN THE TREATMENT OF ANEURISM.<sup>1</sup>

Dr. O. K. NEWELL: The chief thing that strikes me as of interest in this paper is the system of carrying out the preliminary pressure for the development of a collateral circulation. I am sure in what cases of aneurism I have seen treated, where the ligation has been made, preliminary development of collateral circulation has not been undertaken. I do not know that I have ever seen it done as a first step to the operation. I should think it would be one of great importance in avoiding gangrene, and would affect the mortality of cases very much.

Dr. A. POST: I should like to ask how long the patient's syphilis had lasted?

Dr. BEACH: The exact dates cannot be given. The patient was unable to furnish a complete history. The symptoms were ulceration, persistent headache, sore throat, loss of hair. Corroborative of the foregoing, an acknowledgment of the disease. As to the bearing of syphilis upon aneurism, I must confess that I do not believe that because aneurism happens to co-exist in a patient with the history of syphilis, the aneurism must necessarily result from syphilis. The latter, we know, is likely to affect the smaller vessels, whereas atheroma, so commonly associated with aneurism, is more apt to be found in the larger trunks or secondary branches, where also aneurism is frequently found.

<sup>1</sup> Med. Rec. Press. and Circulation, 1890.

<sup>18</sup> Lancet, Nov. 5, 1891.

<sup>1</sup> See page 100 of the Journal.

DR. A. POST: That is an exceedingly interesting subject, namely, the connection between aneurism and syphilis. I hoped Dr. Beach had some more definite ideas in regard to the time that had elapsed. It evidently is some years in his patient, which is, I believe, the usual interval. Certainly syphilis is but an occasional cause of aneurism, if it is a cause at all. I am a little surprised that Dr. Beach thinks it necessary to take such pains to establish the collateral circulation. The cases upon which I have been obliged to operate in the popliteal region, the lower end of the femoral at least, have been traumatic mostly, and the collateral circulation has established itself very readily, although the operation was done immediately. In only one case out of four did I have any gangrene, and in that case it involved only the toes. That was a case in which the rupture of a vessel was followed by very great swelling before the operation took place.

DR. HOMANS: I have had no experience in the mechanical compression of an artery for the cure of aneurism except as I have seen it practised by others. Of late years I have had very few cases of aneurism at the Massachusetts General Hospital. I remember one quite remarkable case of continuous compressing, where Dr. West sat up a couple of days and nights and etherized the person, and I think the case was cured. I can recall three cases of my own in which the femoral was tied at the apex of Scarpa's triangle, and all did perfectly well. It has always seemed to me that that was the easiest and most successful way of treating an aneurism, as far as my experience and observation have gone. I have lately had a case at the hospital which would seem to show that the preliminary establishment of collateral circulation is not always necessary. A man was brought in who had been hooked by a cow. There was no pulsation in his femoral or in the arteries of his leg. There was a little blood coming out of the serotum. The cow's horn had evidently torn off the right external iliac artery. Pulsation has never returned in the femoral. The man has recovered completely. It is a remarkable case, and one of the class which has been illustrated on a larger scale by the cases of ripping open the pregnant uterus of Indian women by buffaloes, of which Dr. Harris has reported several cases followed by recovery. I only mention this case to show that preliminary establishment of collateral circulation is not always necessary.

DR. BEACH: The question of compression or ligature, in the treatment of aneurism, is so broad in all its bearings, that the success or non-success of a few cases would hardly stand as competent evidence either way. Instead of a small number of isolated cases, examine a series. For instance, one, where out of twenty-two cases of ligature twenty are successful, in which compression had been previously tried unsuccessfully so far as stopping the aneurismal pulsation was concerned, but successful in establishing an adequate collateral circulation and so saving the limb. Again, compare such a series with another of ten cases where the femoral artery was tied without the preliminary compression, and three patients died of gangrene. We know that after ligature pulsation returns. It has done that in a number of cases. Ligature does not do away with pain altogether. It may be succeeded during the establishment of a collateral circulation. The pain in this particular case was not in the neighborhood of the compression. It was in the knee, from the pressure on the adjoining nerves of smaller vessels

which were becoming enlarged. It was the pain incidental to the establishment of a collateral circulation.

DR. W. F. WHITNEY presented the subject of

THE PATHOLOGICAL ANATOMY OF THE APPENDIX CÆCI, WITH SPECIAL REFERENCE TO ACUTE AND CHRONIC APPENDICITIS [LANTERN ILLUSTRATIONS].

DR. FITZ: One of the points made by the reader related to faecal concretions. The importance of their presence, he suggested, is perhaps rather greater than is usually recognized. In a considerable proportion of cases they are found, but they are very often seen where there is no appendicitis, and may be present a long time, as one of the photographs showed, where a considerable dilatation had taken place, which was filled with a large concretion. For a mass of that size to have formed must have required a long time. I think Dr. Whitney will agree with me that the special contributions which are to come in the way of the pathological anatomy of the appendix are to be derived from material which is furnished by the surgeon, such as he has collected and is now examining. The pathological anatomy of the appendix has hitherto been studied in cases where the patient died during an acute attack, or lived so long that the immediate disturbances were overcome or where the inflammation had undergone practically a spontaneous cure, the vestiges being left behind. In fact, the same sort of history is being gone through with what pathologists have experienced in connection with inflammation of the Fallopian tubes. Such an appendix as he has shown to-night, and which was so illustrative of the changes in chronic appendicitis, is a sort of appendix I do not remember to have seen before the days of surgical operations in this region. The appendices which it is particularly important to see and study with reference to treatment are those of which Dr. Whitney has already a number, where with symptoms of acute appendicitis, very often a primary attack, the appendix after removal shows no perforation. It is very important, if possible to discriminate clinically such cases from those in which a perforation is found, for the indications for operative treatment are much more urgent where perforation exists than where it does not. By comparing the symptoms and the results of the microscopical examinations of the specimens removed at the early operation, we shall very likely get satisfactory evidence for our guidance on this point.

Many of the cases of chronic appendicitis, where there may be ten or twelve attacks in a period of months or years, and where the appendix is removed during an intermission, are undoubtedly cases from which the patient would recover if left alone. The attacks may last only two or three days. The indications for operation in this class of cases have been presented by Dr. Porter in his recent paper. We shall all be much interested to hear the further progress Dr. Whitney makes in these investigations, which will doubtless add materially to our knowledge of the subject.

DR. CUTLER: Amongst the interesting things Dr. Whitney spoke of was one with reference to the difficulty of injecting the appendix from the cæcum. That is in accord with some of the experiments performed by the German observers. Doubtless, Dr. Whitney's further investigations will throw some light on that point.

DR. FITZ: In the appendices of infants and young

children the existence of a valve has been described by Gerlach, and spoken of in many of the works as explanatory of the greater frequency of appendicitis in young children. I think Dr. Whitney found it difficult to inject the appendix not only in young children, but in older children.

DR. CUTLER: I think that was the case with the observers I have alluded to. They took appendices from persons of the ages usually affected by appendicitis.

DR. MUNRO: I think Quain speaks of a valve existing in the appendix of the adult.

DR. FITZ: Dr. Munro will probably agree that it is very difficult to find in the adult a valve in the appendix.

DR. MUNRO: There is a valve-like opening.

DR. FITZ: I have often sought to demonstrate a valve in the appendix of the adult, and have never seen anything that deserved the name of a valve.

DR. CUTLER: Is there anything in the anatomy of the opening in the appendix similar to that in the ilium? If the cæcum be distended, the opening is distinctly a slit, and the tighter you distend it the more distinctly slit-like it is, as one sees it after death. Does that same condition obtain during life?

DR. WHITNEY: I think not. In reference to the valve which Gerlach mentions, I am not sure that I know exactly which it is. The number of folds varies greatly at the opening of the appendix, but there is one that usually covers it to a greater or less extent in every case. This in moderate distention of the intestine is pressed over the opening, but in hyperdistention of the gut is forced open again, as can be seen in the specimens injected with alcohol under pressure.

DR. BEACH: As demonstrator of anatomy at the medical school for some years, I can testify to the difficulty with which the appendix is injected from the intestine. With reference to the matter of concretions, I reported a case twenty years ago in the *New York Medical Journal*, where, at the autopsy of a patient of the late Dr. Hosmer, I found a concretion at the sloughing end of the appendix lying in a bed of pus. Upon careful examination, the concretion proved to be made of oat-meal hulls cemented together by fecal matter. The mass was very hard, and from its surface projected many needle-like points.

DR. O. H. MARION reported

#### A CASE OF TUBAL PREGNANCY.

The patient, a married woman, thirty-four years of age, had always been well until a week ago last Saturday, when she was taken with sudden pain with urgent desire to go to the water-closet. While there she fainted. When I saw her a little later, there was tenderness over the right ovary. The next day she seemed quite comfortable excepting the pain in the abdomen on the right side, and feeling faint on any motion. That night I was called at 7:30 and found her in a state of collapse. Reaction took place after three hours, at which time she said she never had such pain in her life. Monday morning there was felt through the vagina a little mass at the back of the uterus and a little to the right, non-fluctuating and non-pulsating. Pressure on it made her faint and hurt her quite a little. Tuesday morning she looked badly bloated, and as I drew her water that morning the part about the vulva seemed very pale. I made another examination and again felt this mass. I

thought I had to do with internal hemorrhage and, possibly, tubal pregnancy. My brother saw her in consultation, and was of the same opinion. That afternoon Dr. Baker saw the case, confirmed our diagnosis, and advised operation, which was done Wednesday morning.

DR. BAKER: The case was very interesting from the fact that there had been no irregularity in her menstruation. The menstruation had occurred last on March 12th, and had been regular in February and January. In February and in March there had been, after the regular flow, a little dribbling for several days; and after the period in March this had gone on for ten days or two weeks. There had been noticed no shreds discharged in the flow, and none of the other symptoms of early pregnancy. The absence of the ordinary symptoms, the suddenness of the attack, the great collapse, were the marked things in the case. The vaginal examination showed a soft mass at the right and a little behind the uterus, which deflected the uterus off towards the left. I felt that we had to deal with a case of tubal pregnancy, and an operation was done. The operation was rather a tedious one, from the fact that so much of the broad ligament had to be stitched like a saddle stitch. The amount of clots turned out of the peritoneal cavity was very great. The cavity was thoroughly washed out and closed, and the patient has done very well.

DR. WHITNEY: The point of interest in the specimen was the size, and the possibility of making the diagnosis of its age. It was not much larger than the end of the thumb, and the microscopic examination showed very imperfectly formed villi. We have no absolute date as to menstruation. There is nothing in the specimen that would be incompatible with thinking it was over three or four weeks at most in formation. Of interest is also the fact that in the ovary removed there was quite a large retention cyst, and no corpus luteum that would point to pregnancy. If this is a case of Fallopian pregnancy, it must be one of migration of the ovum across the abdomen from the other side.

DR. FITZ: Were the clots in the abdomen sufficient to give rise to dullness on percussion before the operation?

DR. BAKER: There was over the lower hypogastrium decided dullness. I remember percussing there first and then using the catheter, and still finding dullness on percussion. The whole of the pelvis seemed to be filled with clots.

DR. STRONG: There is very little to add to the description of the patient's condition at the time I saw her, additional to what has been said by Dr. Baker and Dr. Marion. One point is interesting with regard to the examination which I made when the patient was etherized just before the operation; that is, the location of the tumor was distinctly to be felt through the vagina on the right extending behind the uterus, feeling about the size and shape of a Bologna sausage, but in pressing down upon the abdomen I could make out no upper limit to the swelling. The thing that impressed me very much about the case was the typical history, — pain, faintness and collapse.

To-day I saw another case with exactly the same typical history, in the Out-patient Department of the Massachusetts General Hospital. This woman had passed over one period; then menstruation returned, as she supposed, and she had been flowing for about a

month, a little each day. Two days ago, early in the morning, while lying quietly in bed, she was awakened at 5 o'clock by most terrible pain, which she described as in the left side, from which she fainted. After recovering consciousness she got up and moved about the room, and fainted twice more. The rest of the day she spent in bed. This morning she complained of a good deal of pain and tenderness, and I could feel on the right side a mass which, without ether, exactly simulated the mass felt in Dr. Marion's case with this exception, that the external hand found no effusion of blood or fluid masking the upper abdominal border of the tumor. The patient's condition showed that there had been no serious hemorrhages. If in this case, which from its history is so strongly suggestive of tubal pregnancy, there has been a rupture, then the blood is entirely confined within the broad ligament.<sup>2</sup>

DR. CABOT showed a specimen of

#### FIBRO-MYOMA OF THE UTERUS REMOVED BY HYSTERECTOMY.

The tumor had existed for a number of months, but only within three months had it been associated with severe hemorrhages from the uterus. The condition explained this history very well; the tumor was an intramural fibro-myoma, which had recently broken through and projected in a polypoid form into the canal of the uterus. The hemorrhages, no doubt, had followed since the breaking through of the tumor into the cavity of the organ. The operation was followed by uninterrupted recovery, and the patient has already gone home well.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED Meeting, May 18, 1891, the President, S. B. W. McLEOD, M.D., in the chair.

DR. T. J. MCGILLICUDDY read a paper on

#### THE HUMAN MAMMÆ AND THEIR ANOMALIES.

The first part of it was devoted to a consideration of the anatomy and physiology of the milk glands, as taught by the best and latest authorities. Passing on to their anomalies, the writer said that it was commonly noted that the two mammæ in very many cases were of unequal size. Absence of one, or both breasts, was very rare, but Hutchinson reported a case where both breasts were congenitally absent, and Paull a case where one breast was lacking. Mammæ of infantile size were generally accompanied by some ovarian defect, and, on the other hand, a too early and too great development of the breasts accompanied precocious development of the sexual organs.

Polynazia was much more frequently found than amazia, and supernumerary nipples were said to be quite common. In fact, rudimentary mammæ and nipples occurred, according to some writers, at least once in every five hundred individuals. Excess of formation here had been looked upon by theorists as a return in the direction of an earlier type, or a condition of atavism; and Meckel had stated that the earliest of our species had five mammæ, two pectoral, two axillary, and one near the navel. Extra mammæ were most frequently found in the axillæ or beneath the normal mammæ; but they were also to be met

with in the groins and on the thigh, abdomen, and back. The axillary glands might have a nipple, or only a minute orifice, or again, the milk might exude from several small orifices. Barth reported the case of a girl with a nipple below the lobe of the right ear, and it had an areola and increased in volume during menstruation. The number of these supernumerary mammæ might vary from one to half-a-dozen.

Marked hypertrophy of the nipple alone was occasionally met with, and Dr. McGillicuddy had had a case where the diameter of the nipples was too large for the infant's mouth, and an artificial nipple was required in order that it might suckle. A breast might have two nipples, but absence of the nipple was very rare. Imperfections of the nipple were much more common. Supernumerary nipples and mammæ, according to Sutton, were more common in men than in women. In some few cases the axillary glands were really continuations of the lobules of the mammæ which were prolonged outward beyond the limits of the breast.

The writer referred to several cases of anomaly which had come under his personal observation.

CASE I was that of a woman, twenty-six years of age, in whom the right breast and pectoral region were at least one-half larger than the left; a condition which she ascribed to the fact that she nursed much more frequently from the right breast than the left, on account of the latter secreting but a scant supply of milk.

CASE II. On March 3, 1891, Dr. McGillicuddy attended Mrs. McA., aged twenty-four, in her second confinement. She stated that about the third month in each of her pregnancies, the axillary glands, which previously had been flat and gave her no inconvenience, filled with milk. On examining them, a large brown areola, of a lighter shade than that on the breasts, was found, but no sign of a nipple. The milk, which flowed continuously, but most freely while she was nursing her infant, exuded through the pores of the skin; and the condition was very disagreeable to the patient, as it kept her clothing constantly wet and soiled.

CASE III was seen through the kindness of two medical friends. The patient was a young married woman of nineteen, whose second child was born March 8, 1891. She had not nursed her former child. Four days after labor she found milk flowing from the left axilla, and on examination, two rather large orifices and two or three smaller ones were seen. Through these milk exuded constantly, and in greatly increased quantity when she was nursing.

CASE IV was a single woman, twenty-six years of age, with a supernumerary gland in her right side, extending from the seventh to the ninth rib. It was of an oval shape, following the intercostal space, and for fourteen years had been subjected to the pressure of a corset. During her menstrual periods there was pain in all three mammary glands.

CASE V was a male, thirty-five years old, with two supernumerary mammæ in the abdomen, one on a line with the other a little below, the umbilicus. The nipple of the one on the left side was four and one-half inches, and of the one on the right side three inches, from the umbilicus.

CASE VI was also a male. He was forty-six years of age, and had a supernumerary mammary gland on the thigh, which a sister stated was first noticed at

<sup>2</sup> The patient was operated on two days later in the hospital, and the mass was found to be a small ovarian cyst. No explanation for the patient's history could be found.

birth. It was as large as the normal breast of a young woman, with a perfectly smooth nipple, and its lobular structure could be distinctly felt.

CASE VII was a young man who had a perfect but diminutive supernumerary nipple placed about two inches below the normal nipple on the left side.

CASE VIII, an infant, seven weeks old, had a supernumerary nipple in a very uncommon location, namely, on the chest, midway between the normal nipples. It was slightly larger than the latter.

CASE IX. Miss R., aged twenty-six. Neurasthenic temperament. Very delicate, and frequently hysterical. No glandular development whatever can be detected; the condition being the same as in the male breast, with simply nipples alone.

CASE X. Miss F., aged eighteen. When thirteen years old, as the result, it was supposed, of a blow, the right breast began to develop rapidly, and increased until it reached the normal size in young women of twenty; the other breast in the meanwhile remaining undeveloped. At present the breasts are normal and the same size, and menstruation is regular.

According to Park, there had previously been some fifteen cases of polymastia reported in American medical literature. Operative interference, Dr. McGillicuddy said, was not indicated under ordinary circumstances. The flow of milk in some instances was more or less inconvenient, but belladonna and strapping would probably be all that was required in most cases. The presence of many of the anomalies referred to, was generally not suspected until they were discovered by lactation, and like many other conditions, they were considered extremely rare until they were especially looked for. Photographs or drawings of most of the cases reported in the paper were exhibited.

DR. LEWIS SMITH read a paper on

#### RECENT MODIFICATIONS IN THE TREATMENT OF DIPHTHERIA.

Dr. Smith thought that there was now no question whatever that the Klebs-Löffler bacillus was the true cause of diphtheria. It had also been demonstrated, he said, that this bacillus never penetrates the interior of the body, and that its action is restricted to the surface on which it happens to alight. By its irritating effect it caused the pseudo-membranous inflammation upon the mucous or cutaneous surface, but as it never occurred elsewhere than upon the surface, and so was soon conveyed by the blood or lymph currents to internal organs, it could not in itself produce the systemic infection from which so many victims of diphtheria perished. This was now believed to be caused by a chemical substance generated by the bacillus, and, according to Brieger, composed principally of carbon, oxygen and nitrogen, but also containing a little hydrogen and sulphur. This substance had very poisonous properties, and it was very readily taken up by the blood-vessels and conveyed to every part of the body. It was this which caused the nephritis, granulo-fatty degeneration of the heart-muscle, and other lesions incident to the systemic infection. The extreme contagiousness of diphtheria was well known to the profession, and numerous instances had been reported showing the tenacious attachment of the diphtheritic virus to objects and its prolonged vitality; so that an infected article or room might communicate the disease months or even years after the infection had occurred.

These facts, he said, should be borne in mind in considering the local as well as constitutional treatment. In speaking of the hygienic treatment he said it was often best to aid digestion by administering such pepsin preparation as wine of pepsin or essence of pepsin with each feeding. For patients with feeble digestion the pre-digested foods, such as peptonized milk, beef peptonoids and sarco-peptones, were often very useful. When there was difficulty in swallowing, from the severity of the pharyngitis or from palatal paralysis, rectal alimentation by means of predigested liquid food, administered through an elastic catheter introduced far enough to reach the sigmoid flexure, was called for. Alcohol in some form was useful in all forms of the disease, and in severe diphtheria, as after the bite of a venomous reptile, large and frequent doses of alcohol were required to antagonize the poison. The indication for the use of alcohol was apparent when it was remembered that it had been demonstrated by actual experiment that alcohol diluted to one part in five, applied to the cornea of a rabbit inoculated with the Klebs-Löffler bacillus, will prevent the development of the specific inflammation; destroying the bacillus or neutralizing its action.

In considering the local treatment Dr. Smith said the important fact should be borne in mind that bacteriologists have recently found the Klebs-Löffler bacillus upon healthy mucous surfaces, and therefore without any pathogenic action, in those who have been exposed to diphtheria. From this it was believed that the epithelium in its normal state, without any break or abrasion, whether upon the faucial or other surface, may afford an effectual barrier to the bacillus; but if the epithelium be injured or removed by treatment, traumatism or disease, at the point where the bacillus lodges, inoculation will occur and diphtheria result. Therefore, in the local treatment of diphtheria, such remedies as destroy the epithelium or impair its function should be discarded. It had long been known that in one exposed to diphtheria the specific inflammation attacks, by preference, such surfaces as are already diseased; and hence the opinion, confirmed also by recent observations, was gaining ground in the profession that local treatment which is irritating is injurious. Applications which, while they might destroy the pseudo-membrane, also destroyed the epithelium and underlying tissue, unquestionably did more harm than good.

D'Espine had observed the effect of various agents on the Klebs-Löffler bacillus. Benzoate of sodium, 5 to 10 parts in 100, chlorate of potassium, 5 parts in 100, boric acid, 4 parts in 100, and sulphuret of sodium  $2\frac{1}{2}$  to 5 parts in 100, did not arrest its development. Under similar conditions it was arrested by corrosive sublimate, 1 part to 8,000, by carbolic acid, 1 to 50, by salicylic acid, 1 to 2,000, by chloral, 1 to 200, and by permanganate of potassium, 1 to 2,000. Of these remedies D'Espine especially recommended salicylic acid, as its toxic properties were slight and its application readily made. He would employ it in the strength of  $1\frac{1}{2}$  to 2 parts in 1,000, and even weaker in the case of very young children. Babies applied various antiseptic agents to the cornea of the rabbit after inoculation with the Klebs-Löffler bacillus. A 20 per cent. solution of carbolic acid did not check the formation of the pseudo-membrane; the same was true of five per cent. solutions of citric and acetic acids. On the other hand, bichloride of mercury, 1 to 4,000, alcohol, 1 to

5, chloral, 1 to 50, and boric acid, 1 to 20, prevented the formation of the membrane, and did not irritate.

Dr. Smith said he had for some time employed bichloride of mercury dissolved in water, 2 grains to the pint, or 1 to 3,840. Each fluid drachm contained one sixty-fourth of a grain, and a child of five years could safely take one teaspoonful every two hours; the local effect of the drug being obtained upon the surface of the throat before swallowing. If the child were old enough that solution might be used as a gargle; and in nasal diphtheria it could be injected through the nostrils. Simon, of Paris, particularly recommended salicylic acid in the local treatment, and urged the necessity of prompt and frequent applications, so as to prevent, as far as possible, the formation of the toxic chemical product of the bacilli. The following was the formula which he generally employed for brushing the fauces :

R	Acid. salicylic.	. . . . .	7½ grains.
	Glycerin	. . . . .	600 grains.
	Infusio. eucalypti	. . . . .	300 grains.
	Alcohol, for solution	. . . . .	q. s. M.

When the pseudo-membranes were very thick and adherent, Simon also applied equal parts of chloride of iron and glycerine from two to four times daily. Læffler himself recommended the following gargle for diphtheritic patients :

R	Carbolic acid	. . . . .	15 drops.
	Alcohol	. . . . .	2 ounces.
	Distilled water	. . . . .	5 ounces. M.

Brandy or alcohol, the latter not more diluted than 1 part to 5 of water, employed as a gargle or spray. Dr. Smith thought was apparently deserving of trial.

After referring to various other topical remedies which had been recommended of late, he stated that several years ago he himself had proposed the following combination, which was still used by many physicians :

R	Acid. carbolic.	. . . . .	gtt. x.
	Liq. ferri subsulphatis	. . . . .	5 ℥j.
	Glycerin	. . . . .	3 j. M.

After shaking the bottle, this was to be applied with a large camel's hair pencil every three or four hours to the inflamed surface. At present he recommended that the mixture should be diluted one-half with either glycerine or water, and the results obtained with the application showed that it was deserving of the confidence of the profession. With regard to the peroxide of hydrogen, he said that he had not had much personal experience, though it had been highly praised by some.

Before dismissing the subject of local treatment, he called the attention to the importance of prompt and efficient disinfection of the nares wherever indications of inflammation of the Schneiderian membrane showed themselves. For disinfecting the nostrils a saturated solution of boracic acid might be injected every two or three hours, or half a teaspoonful to a teaspoonful of the bichloride of mercury solution, two grains to the pint, care being taken that in the nasal and pharyngeal use of this agent, the quantity employed should be within safe limits.

Recent discoveries in reference to the cause and nature of diphtheria, although they showed the importance of early and efficient local treatment, indicated also the need of proper internal medication. The rapid and progressing deterioration of the blood in severe cases called especially for the use of iron, which, by its effect on the red blood corpuscles, the carriers

of oxygen, increased the functional activity of organs and improved the general health. The tincture of the chloride of iron, inasmuch as it had a large percentage of iron, was quickly absorbed and assimilated, and produced a very beneficial local action on the inflamed surface, was commonly employed; and in those old enough it could be used as a gargle before it was swallowed. At the present time it was generally prescribed in hourly doses, in glycerine and water, of from three to ten drops according to age. It should not be given from a metallic spoon.

With the exception of the tincture of the chloride of iron, chlorate of potassium had probably been used in America more than any other medicine in diphtheria : but Dr. Smith thought a strong and altogether sufficient objection to its use was the fact that it was highly irritating to the kidneys, which in diphtheria are very liable to inflammation of a dangerous type. It seemed to him there could be little doubt that it had often been an important factor in producing or aggravating diphtheritic nephritis, of which not a few patients perished. Of vegetable tonics, quinine had been most frequently prescribed, but it was now generally admitted that that there was nothing in the action of this or similar agents destructive of, or antagonistic to, the diphtheritic virus. The benefit obtained from it was chiefly as a general tonic. Large and frequent doses did not apparently diminish the blood-poisoning in severe cases, or exert any controlling action on the cause of the disease, such as was obtained from germicide remedies. While quinine was often prescribed as an antipyretic in febrile and inflammatory diseases, the temperature in diphtheria, after the first two or three days, was not often so elevated that an antipyretic was needed.

As to the bichloride of mercury, he believes that statistics continue to show that when administered internally in safe doses, as well as when prescribed for local use, it aids in controlling the disease and in saving life. Employed internally it could be useful only in antagonizing or destroying the toxic albuminoid generated by the bacillus; and care should be taken that it should not be given too freely. In ordinary cases the following might perhaps be regarded as about the proper quantity which should be administered, in divided doses, in twenty-four hours. For a child of two years, one-sixth of a grain; for a child of four years, one-quarter of a grain; for a child of six years, one-third of a grain; for a child of ten years, one-half of a grain. A very good way of giving it was as follows :

R	Hydrag. chlor. corrosiv.	. . . . .	gr. j.
	Alcohol	. . . . .	5 ℥j.
	Ellixir bismuth. et peisin,	q. s. ad.	5 ℥iv. M.
	Sig. One teaspoonful every four hours.		

As to the time that the bichloride treatment should be kept up, in ordinary cases, it should probably be discontinued after one week, and sooner if diarrhœa occurred.

While calomel had been longer employed in the treatment of diphtheria, and was still recommended by some physicians of experience, the majority of the profession very properly, in his opinion, disapproved of its use; believing that it tended to weaken the patient and increase the anæmia. There was one use of calomel, however, to which he desired to call special attention. During the last few months at the New York Foundling Asylum the inhalation of the vapor produced by the sublimation of calomel had apparently proved a powerful auxiliary to intubation, and in some

cases prevented the necessity of intubation. As soon as hoarseness was observed in a diphtheritic case the child was placed in its crib, and a tent made over it about three feet in height by a sheet placed over sticks fastened to the corner posts. Placed in a wash-bowl, below the feet of the child, an alcohol lamp was ignited, and over it, upon a dish, ten to forty grains of calomel were slowly vaporized. This was repeated every two to four hours, according to the urgency of the case. A Sister of Charity and nurses in the ward had been salivated; but, so far as known, the patients had not been injured. On the other hand, in some instances patients recovered without tracheotomy or intubation, when, from the persistence of obstructive symptoms it was highly probable that pseudo-membrane had formed in the larynx. It was also a fact that since the vapor of calomel had been used in this institution the percentage of recoveries after intubation had been greater than previous to its employment. Of course it was necessary to use so powerful an agent with great caution.

Having remarked that in diphtheritic nephritis the best results were met with from tincture of the chloride of iron, Dr. Smith concluded with a few remarks on the treatment of diphtheritic paralysis.

DR. S. G. COOK said that for more than thirty years he had depended on a single remedy in the treatment of diphtheria and that was the biniodide or red iodide of mercury. He treated the disease as a blood-poisoning, and believed that the mercury antidoted the poison. Hence, he did not trouble himself about gargles, swabs or inhalations. He did not suppose that the red iodide of mercury was probably any more efficacious than the bichloride; but the former had proved so trustworthy an agent in his hands, that he did not like to give it up for anything else. When he was just commencing to practise he had found it very satisfactory in two or three epidemics of great malignancy, and he had continued to use it ever since. He was accustomed to give two grains of the first trituration of biniodide of mercury, equal to about one-fiftieth of a grain, every two hours.

DR. GEORGE E. HUBBARD spoke of the great efficiency of solution of chlorine, made from chlorate of potassium and muriatic acid, with perchloride of iron. It had a remarkable local effect, and was also very useful internally.

DR. LOUIS FISCHER said that of late he had met with extremely good results from the local injection with a hypodermic syringe of about six drops at a time of chlorine water. He had never seen any injurious effects produced by this method.

DR. J. MOENT BLEYN thought that in every case of diphtheria, whether the nasal passages were implicated or not, it was very important to wash out the nose at once in order to prevent infection as far as possible. This could be accomplished by means of a fountain syringe, and the procedure should be repeated as often as the circumstances of the case required. As a stimulant he believed that in time pure ozone would be found preferable to alcohol.

DR. SMITH closed the discussion with a few remarks, and in the course of them he stated that in convalescence from diphtheria perhaps the best preparation of iron was the elixir of the peptonate.

THE late Mr. W. H. Gholstone suffered from a brain tumor, and died from the effects of an exploratory operation.

# TREATMENT OF EPILEPSY BY THE CONJOINED EMPLOYMENT OF BROMIDE OF POTASSIUM AND OF AN AGENT CAPABLE OF RENDERING THE NERVOUS CENTRES ANÆMIC.

UNDER this head, Poulet, of Plancher-les-Mines, in the last *Bulletin Général de Thérapeutique*, writes of a combination of bromide of potassium with Calabar bean, which has given him success in the treatment of obstinate cases of epilepsy where the bromides alone had failed. A favorite formula of his is the following:

R Bromide of potassium . . . . .	100 parts.
Tincture of Calabar bean . . . . .	35 "
Water . . . . .	470 "

Dose. — A tablespoonful, to be increased to a tablespoonful and a half, then two tablespoonfuls, daily.

A tablespoonful contains  $3\frac{1}{2}$  grammes (or about 57 grains) of bromide and 1.08 grammes of the tincture. The medicine may be given in divided doses instead of in one full dose, half a teaspoonful being given at first twice, then three times, then four times a day.

Poulet reports five obstinate cases treated in this manner. These were cases where bromide alone failed to cure.

In No. 1, the fits were formally six or eight a week (*grand mal*). After a year of the new treatment, no return of the epilepsy. In this patient, the tincture of Calabar bean is occasionally replaced by eserine, in the dose of one milligramme to each gramme of bromide; the result has been the same. No contraction of the pupil has been observed during the administration of the medicine.

No. 2, a most obstinate case; had been epileptic for eight years. Eight or ten fits a day. Failure of bromides, given alone, also of bromides and picrotoxin. Definitive cure under bromides associated with tincture of Calabar bean.

No. 3 was also a case of chronic, inveterate epilepsy. Several months' treatment by the combination above specified has given exemption from all convulsive accidents.

No. 4 was a case of grave epilepsy at the menopause. Frequent daily vertiginous attacks ending in convul-

sions and stupor. At first the disease was successfully combated by bromide of potassium associated with picrotoxine; this combination afterwards failing, sulphate of atropia was substituted for the picrotoxine (six grammes of bromide of potassium, one milligramme of atropine, daily). The latter treatment has been kept up for a year, with complete cessation of the vertigo.

No. 5 was a case of cardiac epilepsy. The *grand mal* attacks were followed by hemiplegia, with stupor and hebetude (*état de mal*). A combination of bromide and digitalis caused disappearance of the epilepsy (eight grammes of bromide, associated with two grammes of tincture of digitalis in divided doses, daily).

Poulet terminates his article by the following conclusions:

The bromides remain the sheet anchor in the treatment of epilepsy, and by the term *bromides* we have especial reference to the bromide of potassium which alone is truly efficacious.

There are, however, a great many epileptics whose attacks are only mitigated or postponed, not completely suppressed, by bromide of potassium.

In such cases, if we associate the bromide with some medicament which possesses properties identical with those of the bromide (that is, being capable of anæmiating and decongesting the nerve-centres and paralyzing the system of voluntary muscles) we generally obtain results which are perfectly satisfactory in essential epilepsy, and even in partial or Jacksonian epilepsy, on condition that, in the latter, we begin by the specific treatment of the determining cause. The substances that have been the most successful are Calabar bean, picrotoxine and belladonna. In cardiac epilepsy, digitalis must be added.

We may indifferently substitute sulphate of eserine for the preparations of Calabar bean, sulphate of atropine for those of belladonna, and digitaline for digitalis.

#### THE ACTUAL NUMBER OF BACILLI IN TUBERCULOUS SPUTUM.

As tubercle bacilli are unevenly distributed in sputum, the common methods of examination afford a very imperfect estimate even of the relative number of the bacilli thrown off by different patients or by the same patient at different times. The method recently described at length by Dr. G. H. F. Nuttall,<sup>1</sup> not only makes it possible to calculate closely the relative number of bacilli in sputa, but allows an estimation of the total number appearing during the twenty-four hours. The method consists, roughly, in taking the total amount of sputum for the twenty-four hours, rendering it homogeneous by caustic potash, heat and shaking, diluting with a measured quantity of water, and dropping by an ingenious apparatus a known quantity for microscopical counting of bacilli.

Three cases are given by the author in which the

number of bacilli passed in the twenty-four hours by patients undergoing the Koch treatment were calculated. In the first case the number expectorated before the commencement of the injections was something over two billion. During the injections with tuberculin the number rose to three and once to over four billion, and after the treatment had been given up returned to a little less than the original number. In the second case the number of bacilli varied between twenty and one hundred and sixty-five million before the injections, rose irregularly to two hundred and eighty million at the seventh injection, and then decreased to two hundred and sixty thousand after the sixteenth.

Two series of examinations of sputum after standing a certain length of time point to an actual multiplication of bacilli in standing sputum. It is also interesting to note that a great rise in the number of bacilli was observed to accompany the appearance of elastic tissue.

The author believes that his method will prove valuable in any experiments where it is desirable to introduce a definite number of organisms into culture media, disinfectants, etc. In point of accuracy it certainly far surpasses the loop method generally employed, one of the principal advantages being the saving of time. With such organisms as the tubercle bacillus this method will enable the experimenter to determine the number he is inoculating into an animal with a degree of certainty that has not been possible hitherto. Inoculations made under such conditions will clearly show the difference in degree of virulence possessed by various organisms, as also the relation between the number of bacteria introduced and the progress of the disease. This method brings us moreover a step nearer to solving the problem of the significance of involution and degeneration forms of bacteria.

#### MEDICAL NOTES.

PROGRESS IN MEDICAL EDUCATION IN NEW YORK. — According to the *Medical Record*, the Medical Department of the University of the City of New York makes certain special announcements this year which should have a very general interest, indicating as they do a decided advance in educational methods: First, the faculty have placed the college upon a true university basis; that is, the pecuniary interests of the college have been put entirely in the hands of a body separate from the faculty, while the latter receive fixed salaries, and are free to give their time and energy to advancing the standard of the curriculum unincumbered by financial care. This step makes the faculty quite independent of the number of students who may attend the college classes. A second change consists in making three years' course obligatory; and a third, perhaps the most important of all, consists in the introduction of the recitation system in place of the didactic lecture during the first and part of the second year.

<sup>1</sup> Johns Hopkins Hospital Bulletin, No 13.

#### MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

—The following changes have been made in the faculty: Dr. G. E. Stubbs, Emeritus Professor of Clinical Surgery; Dr. W. S. Stewart, Emeritus Professor of Obstetrics and Clinical Diseases of Women; Dr. H. E. Goodman, Honorary Professor of Surgery, Clinical Surgery and Orthopedics; Dr. J. M. Anders, Professor of Principles and Practice of Medicine, Clinical Medicine and Hygiene; Dr. E. E. Montgomery, Professor of Obstetrics and Gynecology; Dr. Ernest Laplace, Professor of Surgery, Pathology and Clinical Surgery; Dr. W. F. Waugh, Professor of Clinical Medicine.

**INSPECTION OF PORK IN CHICAGO.**—The inspection of hog products at the stock-yards in Chicago is in operation, and in a short time every hog killed in Chicago will, it is hoped, bear the government stamp attesting its freedom from trichinae. At present thirty microscopists are employed and a piece of the diaphragm is the part usually selected. Already many hogs have been condemned, though only a small portion of the daily output is submitted to such examination.

**A SYSTEM TO DEFAUD INSURANCE COMPANIES.**—There is said to be a gang in Paris, the members of which thrive at the expense of the insurance companies. Their plans are simple. A man lets himself be run over. The driver is his accomplice. The authorities are appealed to. An insurance inspector reports on the case, making the slight injury sustained appear a very serious one. The profits are divided up. As occurrences like this became frequent, suspicion began to be aroused. The result was an inquiry, ending in the imprisonment of sixty-five people who were members of the gang.

**A TETRATOLOGICAL CURIOSITY.**—The *Semaine Médicale* contains an interesting description of some "Siamese Twins" which have been exciting the curiosity of the Parisians. Two girls, born in Bohemia, are welded together at the posterior part of the pelvis. Below this point, the condition of things is unique in more than one respect. At first sight there appears to be only one urethra, one vulva, and but one anal aperture. Although there is only one urethra, there must be two bladders, because the desire to pass water does not present itself simultaneously in both subjects. Again, though there is but a single vulva, there are two vaginas completely separated from each other by a well-defined septum and guarded respectively by separate hymens. The rectum is apparently unique for some distance up, for the desire to defecate is common to both subjects, but there are evidently two sets of large intestines. The anus, clitoris, and urethra are arranged antero-posteriorly, but the two vaginas are side by side. Apart from this partial identity of structure, there are two distinct individualities, and one is able to go to sleep while the other keeps awake. The two heart beats are not synchronous, and the sensation of hunger, thirst, etc., are not experienced simultaneously.

**A BABOO'S PETITION.**—The following petition, addressed by an East Indian "baboo" to the English governor, appears in the *St. James Gazette*: "Respectfully Sheweth. That your honor's servant is poor man in agricultural behavior, and much depends on season for the staff of life, therefore he prays that you will favor upon him, and take him into your saintly service, that he may have some permanently labor for the support of his soul and his family; wherefore he falls upon his family's beuded knees, and implores to you of this merciful consideration to a damnable miserable, like your honor's unfortunate petitioner. That your lordship's honor's servant was too much poorly during the last rains and was resuscitated by much medicines which made magnificent excavations in the coffers of your honorable servant, whose means are circumsized by his large family, consisting of five female women, and three masculine, the last of which are still taking milk from mother's chest, and are damnable noiseful through pulmonary catastrophe in their interior abdomen. Besides the above named, an additional birth is, through grace of God, very shortly occurring to my beloved wife of bosom. . . . That your honor's damnable servant was officiating in several capacities during past generations, but has become too much old for espousing hard labor in this time of his bodily life; but was not drunkard, nor thief, nor swindler, nor any of these kind, but was always pious, affectionate to his numerous family consisting of the aforesaid five female women, and three males, the last of whom are still milking the parental mother. That your generous honor's lordship's servant was entreating to the Magistrate for employment in Municipality to remove filth, etc., but was not granted the petitioner. Therefore your generous lordship will give to me some easy work, in the — Department, or something of this sort. For which act of kindness your noble lordship's poor servant will, as in duty bound, pray for your longevity. I have the honor to be, sir, your most obedient servant, —, Candidate."

#### NEW YORK.

**CROTON WATER.**—Complaints came from various parts of the city that a curious and unusual taste exists in the drinking-water. The reason assigned for it is that in some manner the source of supply has become contaminated, and persons residing in the neighborhood of Croton Lake are said to be alarmed at the presence of miasmatic influences there. The water being extremely low, miles of mud flats are left exposed to the action of the sun, and decaying vegetable matter and dead mussels fill the air with a nauseating effluvia.

**HYDROPHOBIA INOCULATIONS.**—There are at present being treated at the Pasteur Institute in West Tenth Street, six new patients from Massachusetts. A man from South Framingham and three children from Ashland were all very severely bitten by the same dog, a large collie, which was finally killed by a brother of the children, with a base-ball club, and which Dr. Gihier believes was undoubtedly suffering from rabies.

BEQUESTS TO INSTITUTIONS. — By the will of the late David Steward \$5,000 is left to St. Luke's Hospital, to endow a bed in perpetuity; and by the will of the late Charles Wm. Merrill, \$5,000 is left to the House of Rest for consumptives. Among the bequests of the late Hector C. Havemeyer are the following: \$35,000 to the Manhattan Eye and Ear Hospital, \$10,000 to the New York Eye and Ear Infirmary, and \$5,000 each to the Presbyterian Hospital and the New York Post-Graduate Medical School and Hospital.

### Miscellany.

#### TREATMENT OF CONSTIPATION IN CHILDREN BY ABDOMINAL MASSAGE.

KARNITZKY<sup>1</sup> describes this method of treatment, in both acute and chronic constipation, in children from eight to eleven years of age.

He concludes that abdominal massage may produce effects upon the alimentary tract, in connection with digestion, which are not inferior to those produced by purgatives. Habitual constipation may be easily cured by massage without the aid of purgatives, and the more readily the younger the child. The younger a child is the milder should the manipulations be, and the shorter the *séances*, which should be from three to ten minutes according to the age of the patient. Longer *séances* are inadvisable, and may even be harmful and aggravate the condition of the patient. Abdominal massage may be regarded as the best means of treating constipation in children. Purgatives should only be used in exceptional cases.

#### CENTRIFUGAL FORCE IN CLINICAL DIAGNOSIS.

In the *Congress für Innere Medizin*, in Wiesbaden, Litten gave an account of a method which had been devised for the adaptation to clinical medicine of the uses of centrifugal force, which have hitherto been applied only by physiologists.<sup>2</sup> The usual methods of filtering, and of allowing fluids to settle, have often certain manifest disadvantages, and these are thus overcome. Special reference is made to examination of the urine, and the ease with which tube-casts, tubercle bacilli and other micro-organisms, blood corpuscles, etc., may by this means be detected. It is applicable, also, to the investigation of fluid from echinococcus cysts and of pleural effusions.

The advantages with regard to the latter are thus stated: "Easier demonstration of tubercle bacilli. Constant demonstration of blood in clear pleuritic effusions. Avoidance of the coagulation of the exudation. The last is specially important; for, as is known, there are some pleuritic exudations which coagulate immediately, so that microscopic examination of them is impossible. If one warms the glass of the centrifugal machine, and allows the fluid to run into it, and sets it at once in motion, the corpuscular elements are obtained before coagulation occurs."

<sup>1</sup> Journal de Médecine, March 15th.

<sup>2</sup> Wiener klinische Wochenschrift, June 4th.

#### THE TREATMENT OF ACUTE ANGINA.

In the *Journal de Médecine* for April 10th,<sup>1</sup> Dr. Capart publishes the following methods of treatment which he employs in different forms of angina. In acute suppurative tonsillitis he causes the patient to suck small pieces of ice and orders twenty grains each of powdered salol and milk-sugar to be divided into six powders, three to be taken each day; or an equivalent amount of salol may be made into an emulsion with gum-arabic and given according to the same directions. In addition, he prescribes a gargle composed of fifteen grains of salicylic acid, seven and one-half grains of acetate of sodium in nine ounces of distilled water, flavored with a little syrup. As a prophylactic measure against the return of abscess in the tonsils, he advises the patients for at least a month to use a gargle of a weak solution of alum containing a few drops of carbolic acid, or the following gargle may be employed:

R Crystallized carbolic acid, . . . . . 5 i.  
Absolute alcohol, . . . . . 5 v.  
Essence of mint, . . . . . 10 xv.

Of this solution ten drops are added to half a tumblerful of water, and used as a gargle morning and evening.

In simple catarrhal angina he prescribes the following potion:

R Borax, . . . . . 5 i.  
Salicylate of sodium, . . . . . 5 ss.  
Decoction of marsh-mallow, . . . . . 5 i.  
Flavor with syrup.

If a cure does not take place within twenty-four or thirty-six hours he then has recourse to a slightly astringent gargle, such as the following:

R Calcined Alum, . . . . . gr. xl.  
Alcohol, . . . . . aa 5 iiss.  
Pure glycerin, . . . . . 3 i.  
Water, . . . . . 3 x.

To be used as a gargle four times daily.

He cautions in the strongest terms against the use of concentrated solutions of tannin or alum.

#### THE PREPARATION OF SPONGES FOR USE IN SURGERY.

WAYLAND, in the *Annals of Surgery*, Vol XIII, No. 5, considers the best methods of rendering sponges absolutely sterile.<sup>2</sup>

He finds that sponges of close texture, even if soaked in a solution of carbolic acid up to the strength of 1 to 40, are not rendered sterile throughout. The central portions of such sponges, if planted upon nutrient gelatin, show abundant growths of putrefactive microbes. Again, the ordinary surgical sponge, impregnated with foul discharges and thoroughly cleansed with a solution of carbolic acid, likewise exhibits, when implanted upon nutrient gelatin, abundant growths. If, however, a solution of 1 to 2000 bichloride of mercury is employed, such sponges remain entirely sterile. The small cut Turkey sponges are the best, because, though their texture is close, their shape prevents them from being anywhere so thick as to prevent the thorough penetration of the antiseptic solutions.

The question of the proper manner to store sponges is one of extreme importance. A number of sponges were kept for nine months, some in a solution of 1 to 20 carbolic, others in a solution of 1 to 500 bichloride.

<sup>1</sup> Therapeutic Gazette, June.

<sup>2</sup> American Journal of Medical Sciences, July.

Both sets were darkened; but neither suffered in consistence, and even by microscopical examination no changes in texture could be detected. The sponges will in time darken, not from being actually dirty, but from the process of pigmentation. It would seem, then, that after the sponges have been thoroughly cleansed, storing in 1 to 500 bichloride solution renders them absolutely sterile and does not impair their useful qualities.

The author has usually employed the hyposulphite process in preparing sponges; that is, the sponges are first steeped in a hydrochloric acid solution, 1 to 10, then immersed in a bath composed of hyposulphite of soda one part, hydrochloric acid two parts, water twelve parts. This solution is then pressed out, and the sponges are well washed in cold water. They are finally placed in a bath containing half an ounce of carbonate of potash.

Objection is raised to using the sponges more than once, since while it is quite possible to render a septic sponge aseptic, there is no means of knowing whether or not ptomaines or toxic albumoses may be present, and there is no known agent which can be relied on to counteract the possible toxic effect of such substances.

### THERAPEUTIC NOTES.

**STRYCHNINE IN DIPHTHERITIC PARALYSIS.**—Rosenzweig<sup>1</sup> reports very good results from the hypodermic injection of strychnine in paralysis following diphtheria. He tried it in four cases, in doses of two to three milligrammes, with the effect of causing the nasal speech and difficulty of swallowing to disappear rapidly. This treatment was originally proposed by Hensch, and, the writer thinks, has not received the attention it deserves.

**A LINIMENT FOR ECZEMA OF THE ANUS AND SCROTUM.**—Unna recommends the following:<sup>2</sup>

R	Olei Lind.	}	. . . . . 55 3 j.
	Aque calidis		
	Zinci oxidi		
	Iodoform		. . . . . 3 iss. M.

**STOMATITIS IN CHILDREN.**—Where the trouble is extensive and painful the *Province Médicale* recommends the following treatment:

(1) The gums should be brushed with

R	Coraline hydrochlor.	. . . . . gr. iss.
	Sodu chloridi	. . . . . gr. xv.
	Glycerini	. . . . . 55 3 iss. M.
	Aspini	

Use a camel's hair brush.

(2) A spray of a solution of boracic acid should be frequently used.

(3) Bromide of potash internally.

**TREATMENT OF ERYSIPELAS.**—Dr. Ch. Ulrich reports the results given by three modes of treatment adopted in a series of eighty-nine cases of facial erysipelas, namely, ice compresses, tar preparation and ichthyol collodion. He found that, having respect to the spread of the rash, the formation of bullæ, recrudescence, and the duration of the disease, the third proved the most effective means of treatment. He notes on the importance of applying the collodion in

a broad band, beyond the edge of the rash. The collodion consists of

R	Ammonii sulpho-ichthyolat.	}	. . . . . 55 3 ss.
	Etheris		
	Collodii flex.		. . . . . 3 j. M.

**HYDROCHLORATE OF OREXIN.**—Gordon<sup>4</sup> gives his results in a paper on this drug. The full chemical name is hydrochlorate of phenyl-dihydro-quino-azoline. It was introduced by Professor Penzoldt of Erlangen some time ago as a pure stomachic, for which he claimed that it increased the appetite, aided digestion, and stimulated absorption of the products of digestion. It occurs in colorless crystals, which are to a certain extent soluble in water. The taste is sharp, pungent, and somewhat acrid, giving a slightly burning sensation to the tongue. The drug may be given either well diluted in water or made into pill form with any of the ordinary excipients, and can also be given between thin slices of bread or butter or in the form of wafers. The adult dose was stated by Penzoldt to be from three to five grains. The dose given by the author is one-quarter of a grain three times a day, before food. After a summary of cases, both adults and children, the author says that it would appear that orexin is, in the loss of appetite concurrent with tubercular disease, a valuable stimulant. The power of stimulating absorption of the products of digestion claimed for it seems to be merited, for under its use, as a rule, the tongue became less furred, and the constipation was relieved. Though, so far, these observations cover only a limited field, still the indications are that orexin is worthy of receiving an unbiased trial in suitable cases.

### Correspondence.

#### DR. ANDREW D. WHITE'S WARFARE OF SCIENCE.

NABANT, MASS., July 24, 1891.

MR. EDITOR: At first I was somewhat annoyed that you should have honored Dr. Andrew D. White's statements on the relation of religion to medicine from his papers in the *Popular Science Monthly*, by embodying them in an editorial in your number of July 16th. It is, however, for the best. It gives me the opportunity of exposing a series of gross misrepresentations and of absolutely false statements which may deceive many. The questions which particularly concern me are those connected with the relation of the Catholic Church to medicine, especially in the Middle Ages and at the Renaissance. It is necessary for me to show that Dr. White is so absolutely untrustworthy that no statement of his can be accepted without proof. The whole spirit of his article is bitterly prejudiced and unjust. He seeks continually to give the impression that the Church has oppressed medicine. Let us now take up several points one by one.

By a slight alteration, which I am sure was unintentional, you have made one of his statements much worse than it was originally. You say, "The School of Salerno was held in aversion by strict churchmen." Dr. White said, "by multitudes of strict churchmen." . . . This was unlikely, but not impossible. The school was founded by the Benedictines, who certainly were considered strict churchmen. A little later you say, following, I believe, Dr. White quite accurately: "Pope Innocent III, early in the 13th century, forbade physicians, under pain of excommunication, to undertake medical treatment without calling in ecclesiastical advice." In point of fact, what is referred to was not done by Innocent III, but by the Fourth Council of the Lateran, during his reign. That, however, is a

<sup>4</sup> Lancet, July 11.

<sup>1</sup> Theophrastus, de Morb. Acut., Sec. I, § 90.

<sup>2</sup> J. C. M. de Med. et Chir., July 2d.

<sup>3</sup> Theophrastus, de Morb. Acut., July 2d.

detail of little consequence. The point is, first, the entirely false impression that is given, and, secondly, the penalty. What was decreed was, that a physician, on being called to a case, should advise the patient to attend to the state of his conscience, that is, to send for a confessor; but this in no way implied that the priest was to interfere with the treatment of the case. The penalty for not doing this was not excommunication, but prohibition to enter a church, which was a very different thing from excommunication in those days. There is another part of the same canon which Dr. White does not quote, but which is worthy of mention. It was that the physician should advise no remedy for the good of the body that might be to the injury of the soul. The penalty in this case was excommunication. This, indeed, is a check on medicine, but a most salutary one. The talk of Vesalius having been driven to exile and death is absurd. So far from having been oppressed by the Church, he flourished chiefly in Italy and Spain, the two countries in Europe where she was strongest. He professed anatomy at Padua, Bologna and Pisa, apparently going from one to the other. He later went to Spain. He no doubt met with great opposition, but probably chiefly from his own profession. He remained at the Court in Spain for nineteen or twenty years and then set out on a pilgrimage to the Holy Land, returning from which he suffered shipwreck and death at the Island of Zante. There are a variety of rumors as to the cause of this pilgrimage, which I myself investigated some years ago. There are sensational stories of his having by mistake cut into a living man; and, of course, from certain sources there are hints at the suspicion of heresy and the Inquisition. It seems to be all surmise. I could find nothing pointing to clerical oppression. Then again, it was said that he went to escape professional jealousy or to make money or to get rid of his wife. For my part, knowing nothing about it, I incline to believe that he went like many others, because he wanted to. Be that as it may, it is certain that at Jerusalem he received letters from the Senate of Venice offering him the professorship of anatomy at Padua, which disposes effectually of Dr. White's statements about his being driven to exile and death.

I must now dispose of a glaring misstatement of Dr. White's which you do not reproduce. I do so partly from the interest there is in the subject, partly as showing this writer's absolute untrustworthiness.

Dr. White says, "Pope Boniface VIII interdicted dissection as sacrilege, threatening excommunication against those who practised it."<sup>1</sup> This is utterly false. What makes it worse is, that the nature of the decree of Boniface VIII is set forth in its title, which is as follows: "*Corpora defunctorum exenterantes et in inhumat deoquentes, ut ossa a vultibus separata ferant sepelienda in terram sum, ipso facto sunt excommunicati.*" That is to say, it forbids the eviscerating and boiling the bodies of the dead for the purpose of bringing the bones home to the country of the departed. This is a custom which appears to have sprung up, or at least been in use, during the Crusades. Neither in this decree nor anywhere else, so far as I have been able to learn, is there any prohibition of dissection.

Now, as to Dr. White's second conclusion, "that in proportion as the grasp of theology upon education tightened, medicine declined, and in proportion as that grasp was relaxed, medicine has developed," I have something to say. The schools of Salerno, Padua, Bologna, Rome, Naples, Pavia and Pisa, show that the country where medicine, and above all, where anatomy flourished was just where the grasp of theology was strong. Farther, though very probably in some cases abused by individuals, the influence of theology on medicine has been for morality. One instance has been already mentioned; another is the protection of the unborn. I can well believe that where all theological restraint is thrown away, experiments may be tried by which science will prosper at the cost of patients. Reports of such — let us hope untruthful ones — have recently come from Berlin.

Yours truly,

THOMAS DWIGHT, M.D.

## PROLAPSE OF THE SIGMOID FLEXURE INTO THE RECTUM.

Boston, July 24, 1891.

MR. EDITOR:—It is not easy to do full justice to a lecture like that of Dr. T. Lander Brunton, on "Elimination and its Uses in Preventing and Curing Disease," in the limits of your editorial abstract of July 16th. For those who cannot read the whole lecture for themselves, I think it is a pity that the most novel, interesting and practical procedure in the treatment of prolapse of the sigmoid flexure into the rectum should have been omitted from your editorial. Allow me to give you Dr. Brunton's own words:

"I once saw a case of this sort at intervals for two or three years without suspecting its nature. It occurred in a man from New Zealand, who had been accustomed to a great deal of horseback exercise, frequently riding forty miles a day. He began to suffer from neurasthenia, hypochondriasis, loss of appetite, failing strength and emaciation. In fact, he presented almost the typical aspect of the hysterical girls who are so well treated by the Weir Mitchell plan, and in consequence of this I advised him to undergo a course of massage. This he did two or three times with very little good, until, by my advice, he went to Dr. Eccles, who discovered the real cause of his illness, and by the judicious application of massage to the intestines completely restored him to health."

The method is not described, but it probably was a sort of abdominal taxis, so applied as to pull the sigmoid flexure up out of the rectum, concerning which Dr. Humphrey, in the *Lancet* (Vol. I, 1890, page 76), says: "The merit of the early use of anaesthesia and abdominal taxis is, that, while eminently adapted to many, it is hardly likely to be prejudicial to any."

Yours truly,

DOUGLAS GRAHAM, M.D.

## RECORD OF MORTALITY FOR THE WEEK ENDING SATURDAY, JULY 18, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

<sup>1</sup> Popular Science Monthly, June, 1891, p. 155.

Deaths reported 3,883; under five years of age 2,251; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,455, consumption 394, acute lung diseases 225, diarrhoeal diseases 1120, diphtheria and croup 90, typhoid fever 50, scarlet fever 54, measles 36, cerebro-spinal meningitis 25, whooping-cough 22, malarial fever 9, erysipelas 3.

From scarlet fever New York 30, Brooklyn 8, Chicago 6, Baltimore and Cincinnati 3 each, Philadelphia 2, Milwaukee and Springfield 1 each. From measles New York 12, Chicago 11, Philadelphia 3, Brooklyn and Cambridge 2 each, Milwaukee, Charleston, Worcester, Lawrence, Springfield and Chelsea 1 each. From cerebro-spinal meningitis Chicago 7, New York 6, Brooklyn and Washington 3 each, Baltimore and Gloucester 2 each, Worcester and Haverhill 1 each. From whooping-cough Chicago 7, New York 5, Philadelphia, Milwaukee and Washington 2 each, Baltimore, Nashville, Fall River and New Bedford 1 each. From malarial fever New York 5, Philadelphia 3, Nashville 1. From erysipelas New York, Brooklyn and Baltimore 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,465,108, for the week ending July 11th, the death-rate was 16.8. Deaths reported 3,029: whooping-cough 18, diarrhoea 75, measles 66, diphtheria 28, scarlet fever 22, fever 17, small-pox (London) 1.

The death-rates ranged from 12.4 in Norwich to 21.7 in Preston, Birmingham 16.0, Bradford 15.4, Cardiff 20.1, Hull 16.6, Leeds 16.5, Leicester 16.1, Liverpool 20.4, London 16.7, Manchester 19.4, Sheffield 12.8, Sunderland 19.9.

In Edinburgh 16.7, Glasgow 21.6, Dublin 18.8.

#### METEOROLOGICAL RECORD.

For the week ending July 18, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 18, 1891, TO JULY 24, 1891.

ASSISTANT SURGEON WILLIAM L. KNEEDLER, U. S. Army, granted leave of absence for one month.

SURGEON HENRY R. TILLOT, U. S. Army, granted leave of absence for two months, on surgeon's certificate of disability.

CAPTAIN REUBEN L. ROBERTSON, assistant surgeon, U. S. Army, ordered for duty to Fort Niagara, N. Y., on the abandonment of Fort Abraham Lincoln, North Dakota.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 26, 1891.

JOHN G. FIELD, assistant surgeon, ordered to special duty in the Bureau of Medicine and Surgery.

JAMES S. HORN, assistant surgeon, ordered to the Receiving-ship "Franklin."

ELIAS MOERIS, assistant surgeon, ordered to the "Ajax" and other monitors, Richmond, Va.

JAMES T. KLEIN, assistant surgeon, promoted to passed a grand surgeon.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING JULY 18, 1891.

MERRAY, R. D., surgeon. To proceed to Gulf Quarantine for temporary duty. July 1, 1891.

SAWTELLE, H. W., surgeon. Relieved from duty at Portland, Me., ordered to Boston, Mass. July 11, 1891.

IRVING, FAIRFAX, surgeon. When relieved at Boston, Mass., to proceed to Buffalo, N. Y., for temporary duty. July 11, 1891.

CARTER, H. R., passed assistant surgeon. Ordered to Washington, D. C., for temporary duty. July 2, 1891.

BECKHAM, C. T., passed assistant surgeon. Granted leave of absence for seven days. June 30, 1891.

DEVAN, S. C., passed assistant surgeon. When relieved at Buffalo, N. Y., to proceed to Portland, Me., for duty. July 11, 1891.

BROOKS, S. D., passed assistant surgeon. Granted leave of absence for thirty days. July 13, 1891.

KINTOUN, J. J., passed assistant surgeon. Granted leave of absence for thirty days. July 14, 1891.

HOUGHTON, E. A., assistant surgeon. To proceed to Cleveland, O., for temporary duty. July 8, 1891.

#### DEATH.

J. F. GROENEVELT, assistant surgeon, died of yellow fever, at the Gulf Quarantine Station, June 29, 1891.

#### SOCIETY NOTICE.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. — This Association will hold its first annual meeting at the Hall of the College of Physicians, corner Locust and Thirteenth Streets, Philadelphia, Pa., Thursday, Friday and Saturday, September 24-26, 1891, under the Presidency of Dr. G. Betton Massey.

Physicians interested in the discussion of Electricity in Medicine are invited to attend without further notice.

Wm. H. WALLING, M.D., Secretary.  
2005 Arch St., Philadelphia.

#### APPOINTMENTS.

HENRY JACKSON, M.D., has been appointed Physician to Medical Out-Patients at the Boston City Hospital.

J. W. BABCOCK, M.D., Assistant Physician at the McLean Asylum, Somerville, has been appointed Superintendent of the State Asylum at Columbia, S. C.

#### DEATHS.

JOHN P. WELLS, M.D., died in New York, July 22d, aged eighty-six. In the epidemic of 1849 he was placed in charge of the cholera hospital, and before the establishment of the New York Board of Health he held the position of City Physician. He was one of the founders of the New York Academy of Medicine.

CHARLES R. GILL, M.D., formerly of New York, died, July 12th, aged seventy. Dr. Gill had been suffering from cancer of the larynx, making it necessary to wear a tracheotomy tube, which became stopped while he was on a steamboat, causing strangulation before assistance could be obtained.

EDWARD SUTTON SMITH, M.D., died suddenly, July 21st, aged sixty-one. He graduated from Harvard College in the Class of 1853, and from the Medical School in 1856. He had spent several years abroad, and at one time practised in New York.

HERMAN B. SMITH, M.D., of Westville, Conn., died, July 16th. He graduated from the Medical Department of Yale University in 1876.

ALBERT SKINNERR, M.D., of Youngstown, N. Y., the oldest practitioner in Niagara County, died, July 18th, aged eighty-four.

W. WEISS, Professor of Surgical Pathology at the Bohemian University of Prague, died, about July 10th, aged fifty-six.

CHARLES E. SHEPARD, M.D., F.R.C.S., died in London, June 29th, aged thirty-five. He was well-known as an anaesthetist, in which capacity he was connected with several London hospitals. His death was peculiarly sad, being due to mental depression the night after a patient, to whom he was administering chloroform, died from the effects of the drug.

WILLIAM HENRY STONE, M.D., F.R.C.P., F.R.C.S., Physician to St. Thomas Hospital, Croonian, Lambeth and Harveian Lecturer, etc., died in London, July 5th, aged sixty-one.

#### BOOKS AND PAMPHLETS RECEIVED.

## Lecture.

### NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

(Continued from No. 5, page 106.)

*Sense of ill-being.*—But in the conditions, represented by a sense of ill-being, there are feelings of fatigue, depression, anxiety, languor, absence of desires, a sense of lack of power, of self-depreciation, and of personal unworthiness, etc., of which the patient gives account. Beard has well characterized this "as an instinctive consciousness of inadequacy for the task set before us." "We are hopeless," he says, "because our nerve force is so reduced";—"a certain amount of nerve strength is necessary to supply the courage requisite for simple existence." The persistency of these feelings is marked by a visible change of personality. In slighter degrees these changes are like those commonly seen in the evening tire of an active man, from which restoration follows. When, however, in the processes of waste and repair, the balance turns slowly and insidiously to the side of weakness of nervous tissues, whose corresponding mental activities show these symptoms of disability, they stand as evidences of neurasthenic condition. As these morbid physical states persist, the ideas suggested by the morbid feelings, and to account for them, are framed by degrees into some wrong conception. Although there are, however, many cases of melancholia without delusions, yet beliefs may be engendered consistent with the morbid state of hopelessness, self-reproach, and worry. In many cases, special delusions are formed for which the patient gives reasons, with a degree of intellectual integrity that is peculiar to melancholia. These allied organic and consequent mental changes profoundly modify the personality in its inmost nature. By the process described this is not the violent and superficial effect of sudden emotions, but results from a slow and subtle process that irresistibly changes the basis of the personality. It is easy to see how such morbid organic sensations may be engendered in a general neurasthenia and produce such a train of nervous symptoms, characterized by a sense of ill-being, depression and hopelessness. Like results may come from nervous exhaustion initiated in the brain itself, by mental overwork, care and anxiety. Here is the bond between well-being and ill-being of body and the emotional tone. It is plain how the changing states of mental feeling reflect the bodily states in the alterations of the sense of personality.

*Mental Symptoms of Auto-intoxication.*—The new evidence in regard to the toxic elements engendered in the body sustains these views, and seems to offer the long sought explanation of many obscure conditions. Full force should be given to the fact that in all forms of functional activity the fatigue proper, from the discharge of energy and the breaking down of material cell contents, has always joined with it the toxic influence of self-produced waste products. We are able to account for much that appears confusing in the symptoms of fatigue, by ascribing their variations to differences in the kind and quantity of the

specific poisons that are developed in the various tissues. For example, while melancholia is generally characterized by a disposition to quietude and shrinking into seclusion, some cases are marked by great mental agitation and physical restlessness, the essential physical and mental condition being the same. A fair inference is that there is an irritating intoxication in such cases. But again there is the peculiar condition of apparent stupor added to the ordinary melancholia, so that in extreme cases the patient cannot move his limbs or utter a word, and the facial expression is blank. This presents a more profound degree of the condition described by Branton as like the poisoning by curare of the muscular mechanism. "The absence of true psychic stupor in many such cases is well proven. It has been seen that these symptoms may be produced by choline, neurine and muscarine, which are antagonistic to atropine. In Hare's suggestion that it is possible to give relief by antagonistic remedies when there are signs of auto-poisoning, he mentions dilated pupils, a hot and dry skin, dim eyesight, rapid pulse, as like the effects of atropine. Symptoms resembling them in lesser degree are seen in both neurasthenia and melancholia. Again a slow and full pulse with high arterial tension, and a throbbing frontal headache, suggests the ptomaine like digitalin. Some of these poisonous substances lower the temperature; it is often sub-normal in the graver neurasthenic conditions. Upon the basis of such causes, and such a method of production, the "excessive irritability and weakness" of neurasthenia seem amply accounted for. By means of local perversions, the weaker organic sensations sometimes come to be felt, and may be so intensified as to bring them into the group of those that are consciously perceived and localized. Languor, dulness, stupor and lethargy are like manifestations of toxic influences. These altered sensations will be hereafter described. They are of great psychological importance. Reference has already been made to the relation of uric acid to diseases of the nervous system, and the characteristic symptoms of lassitude, depression of spirits, etc. Its formation, elimination, and possible excess in the blood, are so essentially connected with the processes of waste and repair as to make these symptoms most significant in their relation to neurasthenia.

The conditions of mental feeling, marked by the emotional tone, as states of well- or ill-being, have now been shown to be intimately bound up with the great volume of subconscious bodily feelings, and representative of their predominating quality. They are normally so low in intensity as to be undiscriminated; but when intensified by morbid conditions they become symptoms of the existing disorder.

(2) *Sensations from the Special Senses:—Perceptions, Ideas, etc., and Disorders of Intellect and Will.*—It now remains to consider the other group of symptoms representing disorders of the intellect and volition as distinguished from mental or physical feeling. Of these disorders the most important indications pertain to the attention. All writers on neurasthenia have noted the fact that the mental symptoms of the higher order are always prominent. But what is wanted is a sufficient analysis of them to show their two-fold significance. A brief explanation should make this clear, and easy to understand, as it is necessary to be known. On the one hand the disorder may begin below in the sources of organic sensations, and extend

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.

upward into the higher mental sphere. The great mass of sensations beneath are summed up into our sense of physical personality. Compared with them, all that comes, into our conscious minds through the special senses, and the succeeding perceptions, ideas, memories, judgments, feelings and volitions, in the "circuit of consciousness," represents a small item. In acute neurasthenia, and true melancholia and mania, there is always nutritional, toxic and functional weakness, fundamentally, in the organism; it is from this that the influences arise which effect our conscious feeling and thinking, making these higher mental states the sensitive indices of the lower physical changes. For like reasons these subconscious changes of personality, pervading and voluminous, have a predominating influence. When all goes well with the organism, and it is in a condition of unfelt equilibrium, the processes of thinking and feeling are adjusted, more or less logically, to the varying environment, upon a basis of a sense of well-being and normal love of life. On the other hand, a morbid process may be started in these higher activities, in a previously healthy and strong organism; but until the organism itself suffers a change to the specified nutritional and functional weakness, there can be no such mental symptoms as are being studied here. Normal mental activities cannot produce "mental symptoms" except by first causing the characteristic "weakness" somewhere in the physical basis of them all.

**Familiar Facts of Mental Manifestations.** *Consciousness.*—There is no need, in this matter, of entering into psychological speculation. It is only necessary to consider the final facts of the manifestations of mind with which we are most familiar. We commonly note the fact of consciousness for example, and distinguish between such states as its absence in coma, its partial presence in sleep, or its full activity in an alert and intelligent mind when we cannot doubt that some activity of organic elements is added which was not present in the less active states,—as of coma, for example. We use many phrases to describe different degrees of this activity, meaning always a state of consciousness the sum total of all its activities.

*The Attention.*—The attention is the term applied to denote the mental action when a particular object of thought is held in mind to the exclusion of others. Active consciousness is always attending to some one presentation in its field,—this action is attention, and this activity is always going on in connection with every other mental action, or object of thought. The mind may attend to the presented perception of a new sensation,—a representation in memory,—an abstract conception,—or the idea of a muscular movement. The larger importance of the attention is due to the fact that in it resides the inhibitory power over all mental operations. The attention is to these what the physiological principle of inhibition is to the lower nervous mechanisms. It is the abatement of this higher inhibitory power, and of its regulating and guiding control, that appears early and most constantly in mental fatigue and weakness. This is manifested by changes in the power of attention.

Ribot<sup>16</sup> has made very clear, by a simple analysis, the office of the attention. It acts in two forms:—voluntary attention is its acquired form gained as a result of the higher evolution of man;—spontaneous attention is its natural or primary form, when its action

is attracted or reflex, as is so manifest in children and animals.

*Spontaneous Attention.*—Spontaneous attention being first considered, the essential fact is that it is always attracted to the object or idea in the mind that most interests it, or keeps it on the alert. This idea may be intensified in interest by pleasurable or painful feeling,—by a desire or a fear. Now it has been shown that when the emotional tone represents physical well-being or ill-being, ideas harmonious with the emotional tone will be intensified. It has been shown also that in states of ill-being and depression the attention is persistently attracted by painful ideas which are thereby further intensified. Thus a state of habitual mental pain shows attention attracted by, and dwelling upon, painful ideas. This is the basis of worry, and it is thus shown how worry intensifies its own cause. The clinical significance of worry, therefore, is that the weakened attention is being occupied by painful ideas which are intensified by the exaggerated influence of a painful emotional tone representing a weakened and irritated physical basis. The painful ideas are further intensified by the concentration upon them of the attracted attention. When only attracted attention is in action, as in extreme conditions, the spontaneous flow of ideas goes through the mind in a wandering train, as in dreaming or delirium, without check or guidance; and those ideas in the train most attract the attention which are then in harmony with the emotional tone.

*Voluntary Attention.*—The exact antithesis of this is voluntary attention. As to this, the essential fact is, that it is the activity of inhibition. The attention directed and concentrated upon a chosen object of thought is an act of volition. A man controls his own mind by willing his attention, as it were, to be fixed upon some one item or object, in the train of presented ideas, to the exclusion of others. He thinks about what he chooses to think about; he may make the most worthy object the most interesting; by dwelling upon its worthiness he intensifies it, thus resisting the attraction of less worthy interests and emotions. This directing of the attention by the will may control and guide the processes of thinking,—may inhibit the promptings of the emotions in conduct; and it does manifest itself in all voluntary action. Attention has always a motor element and expresses itself in muscular movement. In a healthy man, with a refreshed and vigorous organism, and a trained intelligence and attention, is found the most efficient expression of this higher power of inhibitory and guiding control. This is an acquired power, improved by training. Now it is plain to see the importance of the clinical signs in regard to the higher inhibition. Let there be weakening of nervous energy from any cause, then the weakening of the voluntary attention is a direct and immediate sign of mental and general tire or exhaustion. It may be that, in such a state, as much or more "control" is exercised, but it requires more effort and expenditure of nervous energy.

The more higher control power is lessened, the more the spontaneous attention is left free to act. The gradual reduction of the control power of the voluntary attention is matter of common clinical observation in normal fatigue, neurasthenia, melancholia, etc. Here then is further shown the bond that extends between the changes in the physical basis of the personality and the changes in the higher power of

<sup>16</sup> The Principles of the Attention, Uroos, Chicago, 1890.

attention which thus becomes a sensitive index of bodily conditions. The mental attitude at any given moment is determined by the state of the attention. This is always tending to act in a reflex and spontaneous manner according to the emotional tone, as attracted by the most interesting ideas. When bodily feeling is in equilibrium the voluntary direction of the attention is easiest; but direction is always inhibition,—by will and choice the ideas are held in view that stir the worst feelings, or a consenting will yields to those made interesting by desire. Then feelings as motives add intensification to the mental attitude, and again we find the potent influence of the emotional tone. It controls or is controlled. This brings out the practical point that is of present interest,—the need of the higher inhibitory control and what it works against. According to Foster, just as physiological inhibition plays its part in the lower mechanisms, so is it important in the whole work of the central nervous system. He says,<sup>47</sup> “In all probability many of the phenomena of nervous life are the outcome of a contest between what we call inhibitory, and exciting or augmenting forces.”

Another practical point is of the greatest importance here in regard to the higher inhibitory control, acting through voluntary attention. It is the application of the principles in the laws of practice, habit, and association. The mental activities do not escape the full force of these laws. When once a mental attitude has been determined by the inter-play of ideas, feelings, and controlling or consenting will, there is a functional disposition to repeat the organic and attendant psychological processes. “Habits of thought” are acquired, and they are characterized either by a habit of yielding to impulsive emotion, or as determined by a controlling inhibition. The principle of practice is in like manner always ready to reinforce the power of voluntary attention. Hence we see that the attention, as the agent of the will, has to work against also the effects of practice and habit which tend to become fixed by states of feeling, the associations of which with ideas are also strengthened by habit; while at the same time, voluntary attention trained by practice leads to the highest acquirements of mental power. Conversely, we see the import of the lessening of inhibitory, selecting, and directing power in states of nervous fatigue and exhaustion. Whatever the physician may discover in the bodily condition of his neurasthenic patient, or whatever he may infer of its pathology, he should always remember the effects of habit in the mental activities. The nervous invalid may remain such, even under strongly recuperative tendencies, simply from mental habit, confirming it both by misuse and disuse of normal power. The patient, powerless to contend alone against the forces of weakness and habit, must have a physician for both mind and body.

*Mental Symptoms in Normal Fatigue.*—The fatigue of the attention will vary in its manifestations in different degrees of nervous fatigue and exhaustion. Its predominating significance is also shown by its relation to mental symptoms which may be sufficiently illustrated by a not uncommon experience. Suppose that after a day's professional labor you have spent a long evening at your desk. Your probable mental condition may then be as follows:—There is lessened mental activity. Voluntary attention is fatigued, and

in spite of much effort you repeatedly find your spontaneous attention attracted along some train of ideas to a subject remote from the one you are trying to keep in mind. Sense-perception is less acute,—the attention shows fatigue by inattention to incoming sensations. There is less power of memory,—it is less retentive, because diminished attention to impressions renders them less vivid,—its recalling power is slower and weaker,—and in the underlying association of ideas there is a spontaneous flow which is controlled only by unusual effort of will,—the association process is itself slower, the vocabulary diminishes, and even familiar names and words may not be recalled. The logical processes work more slowly in making comparisons and judgments, and in reasoning to conclusions,—the tired attention with effort holds on to one member of a proposition while another slips away. With growing torpor your attention may cease to be stimulated and you may fall asleep. There is a lowering of the emotional tone and a quietude of feeling with lessening of natural vivacity; there is a diminished sense of adequacy of power, and tasks seem difficult that after rest will appear easy enough. An abatement of power to control the motor mechanism is apparent as requiring more effort of attention. This is normal fatigue; it will be seen that in every phase of these activities the attention shows the effects of fatigue in lessened control. Restoration follows when in the repose of rest and sleep, the circulation removes the acid waste products, etc., that caused the somnolence, while it supplies the materials for rebuilding the cell-contents so that they may again yield energy upon being stimulated.

*Mental Symptoms in the Genesis of Pathological Fatigue.*—When the process of restoration is continuously incomplete, and after a time a similar degree of exhaustion is persistently established, the symptoms may not be quite the same in respect to the toxic influences. It is plain that there will have been going on an active process of removing them, though incompletely; and we have to conceive of a partial inanition and an irritating intoxication as contribution to the “excessive irritability” when it exists, as it commonly does, in neurasthenia. Then the normal fatigue has passed over into pathological fatigue. Recurring now, for example, to the picture of evening fatigue, after a day of hard work both physical and mental, a significant sequel might follow it. Suppose then you are suddenly called to a patient, whose life is in danger. You are aroused. For many hours you may anxiously work over the case with no apparent lack of energy or failure of the resources of your experience and skill. But when relief comes, and you try to get rest in sleep, you only lie awake, restless, your mind excitedly reviewing the scenes you have passed through, your will powerless to inhibit the train of ideas, and you have a painful sense of nervous tension and irritability.

There would seem to be in this condition a ready explanation of acute exhaustion, or excessive fatigue and toxicity. This is the initial stage of pathological fatigue. Such an incident is instructive in many ways. It shows how the store of nervous energy is held in reserve, within the limits of normal fatigue under ordinary stimulation. But unwonted interest being aroused and attention stimulated, the mechanism responds with an increase of cerebral circulation, and large cortical areas are probably excited to action.

<sup>47</sup> Op. cit., p. 918.

While more nutrition is thus taken up, more energy is given out; and although there is a more rapid removal of waste products it is not complete, and these gradually accumulate until some degree of exhaustion is manifested. Then in the search for the power of control over mental processes, the attention failing in its office becomes conspicuous by its absence or lessened power.

The mental mechanism is commonly stimulated to action by the external circumstance, as in the incident just related. The interest excited by the event arouses the attention which, acting in both its reflex and voluntary forms, intensifies all the mental activities. A like experience is still more common, in which there is absence of immediate objective interest, and the mental action proceeds more subjectively and from volition. Take another instance of evening fatigue, and suppose, for example, you have been delaying the writing of a medical paper which must be read to-morrow. With fatigue equal to that yielded to many times before, you approach the task to which a mixed interest is now added by your reflection upon the need of preparation and the consequences of failure to acquit yourself properly. With much effort of will and attention, you apply yourself to the beginning of the mental work. Presently the sense of fatigue and effort has passed away,—the subject itself gathers interest,—and you have a sense of satisfaction in the exercise of mental power. You may desist at last, not with consciousness of mental fatigue, but because the lateness of the hour claims your attention. But as before you may lie awake with an over-stimulated brain and weakened inhibition; and this condition may represent simply a less degree of over-fatigue than in the former instance.

In the first of these two cases, external circumstance furnished the immediate stimulating interest;—in the latter case it is memory and expectation, but the attention is more clearly voluntary and the whole process subjective. In both cases the rôle of the attention is apparent. It becomes evident also that the feeling of fatigue does not measure it, but only represents the fact of fatigue within normal limits, beyond which there is a reserve of nervous energy that may be drawn upon by stimulating the nervous mechanism through an extra effort of voluntary attention. The explanation of the attendant physiological processes throws light upon the whole matter. Ribot<sup>45</sup> says it is highly probable and almost universally admitted, that attention, even when not directed toward any region of the body, is accompanied by local hyperæmia of certain parts of the brain. This result of the greater functional activity is caused by a dilatation of the arteries, which itself is caused by the action of the vaso-motor nerves upon the muscular integuments of the arteries. But the vaso-motor branches of the great sympathetic are independent of the action of the will, and are not influenced directly by voluntary attention; they are, however, subjected to all the influences of the emotions. It is shown by the experiments of Mosso and others that the slightest and most transient emotion causes an afflux of blood to the brain. Munby<sup>46</sup> says, "We may fairly conclude that the effect of attention to a current of thought is to quicken the circulation in the nervous substrata which minister to it, not otherwise than as when some earnest thought

has taken hold of the mind, it keeps up an active circulation in the brain, and will not let us go to sleep."

These considerations enable us to distinguish the main elements of the mechanism that were involved in the last two cases of evening fatigue. In both, interest and emotion were the immediate excitants of the increased blood-supply and brain activity;—in one, the emotion attended the thought of the external circumstance of a patient in danger, and attention was largely spontaneous,—in the other, the emotion accompanied the thought voluntarily chosen to be held in attention, although its interest was more remote. So the attention once becoming active, in whichever form, the same results then followed in either case, and the order was as follows:—attention, intensified ideas with mental feeling of interest or emotion, vaso-motor dilatation, quickened circulation and nutrition, increased expenditure of energy and waste products, and over-fatigue to the degree of exhaustion and irritability.

These phenomena of our commonest experience therefore bear this plain interpretation. It is fundamental in our nature, in the earlier stages of development as in children and animals, that our inner physiological activities and their expression in conduct are largely subject to the feelings,—our mechanisms are driven by untutored interests, emotions or blind instincts. But in the later development of the acquired forces of intellect and will, we control, select, and direct, through attention, the chosen, impelling interests, combined with much yielding and consenting to the primary forces of our emotional nature.

It is a common clinical observation that, with the beginning of failure of higher psychical control, the more mechanical laws of cerebration are brought more freely into play, and we come at last to the phenomena of weakening attention as the index of the more spontaneous flow of ideas along the paths of habit and association. Fatigue of the power of voluntary attention, which goes along with cerebral fatigue, is equivalent to the beginning of the failure of control.

In the mental conditions last described, the symptoms of general and cerebral neurasthenia thus developed reveal the importance of the attention, and the high office of its voluntary power in respect to all mental activities. In the abatement of natural vigor in any of them, the physician should see signs suggestive of neurasthenia.

(To be continued.)

### OBSERVATIONS ON THE SUPPRESSION OF INFECTIOUS DISEASES.<sup>1</sup>

BY J. H. MCCOLLUM, M.D., OF BOSTON.

IN this paper an attempt will be made to show what has been done, in Boston, during the past ten years in the suppression of the three principal infectious diseases, small-pox, scarlet fever and diphtheria, and also to offer a few suggestions regarding the best methods to be employed for this purpose.

At first your attention will be asked to the subject of small-pox; a disease much more dreaded in the

<sup>45</sup> *op. cit.*, p. 19.

<sup>46</sup> *Psychology of Mind*, vol. I, p. 316.

<sup>1</sup> Read before the Massachusetts Association of Boards of Health at Newton, April 29, 1891.

community than any of the other infectious diseases, and without reason, for in no other disease do we have the protective power of vaccination.

When we read the accounts of the fearful havoc that this disease caused before the discovery of vaccination, it is difficult to understand how any sane person can be in doubt for a moment regarding the advantage to be gained by this operation. It is painful to witness a severe case of scarlet fever; an attack of diphtheria is distressing alike to the patient and his friends; but an attack of unmodified small-pox in the amount of actual suffering, in the repulsiveness, in the intolerable odor, and in the subsequent disfigurement far exceeds any of the other infectious diseases. One argument used by the anti-vaccinationists is that small-pox is not so prevalent now as it was formerly and therefore the necessity of vaccination is not so great. This is the very best argument in favor of vaccination, and it proves without a shadow of a doubt the beneficial effects of the operation. Again, the statement is frequently made that vaccination does not protect; this remark is so erroneous, and so entirely without foundation that it seems hardly necessary to attempt to refute it. No man of any experience in the treatment of small-pox has any doubt of the protecting and modifying power of vaccination.

I speak thus warmly in regard to this subject, because I know the immense amount of harm the anti-vaccinationists are doing not only in England but also in this country. It therefore becomes us as officers of sanitary commissions with the public health in our charge, to take a firm and steadfast position in regard to this matter. An argument frequently used by the anti-vaccinationists is, that the vaccine disease is not small-pox modified by its passage through the bovine species, but that it is a separate and distinct disease, and therefore it cannot be protective. The whole theory of the protective power of vaccination, which has been proved by innumerable experiments, is based upon the very fact that it is one and the same disease. An account of the latest experiments bearing on this subject is published in *La Semaine Médicale* of December 31, 1890. The investigators, Professor Eltermod, of the University of Geneva and Charles Haccins, the Director of the Vaccine Institute at Nancy, are men eminently well-fitted to pursue these investigations. Their conclusions are:

"1. Small-pox is inoculable on the bovine species when the method of operation is good and when the virus is taken at the proper time.

"2. Inoculation of the calf with small-pox forms a valuable source, in a new direction, of animal vaccine. This is of great practical value, not only for the vaccine institutions of Europe, but also for those of warm climates, where variola is frequently endemic, and where vaccine rapidly deteriorates.

"3. Variola inoculated on the calf is transformed after several transmissions into vaccine by its passage through this animal. This is not dualty.

"4. Our practical conclusions confirm the ideas set forth by Depaul in 1863, at the Academy of Medicine of Paris."

Dr. Fischer, Director of the Vaccine Institute at Karlsruhe in Germany, performed at about the same time a series of similar experiments and he arrived at practically the same conclusions. This refutes the argument of the dualty of these diseases.

The history of the great epidemic of 1872-73, in

Boston, and the comparative freedom of the city from this disease since that time are most convincing arguments in favor of vaccination.

The operation of compulsory vaccination was suspended in Zürich, Switzerland, in obedience to popular clamor in 1883. The deaths from small-pox, per 1,000 deaths from all causes for the two previous years and that year had been in 1881, 7; in 1882, 0; in 1883, 8. They rose after compulsion had ceased to be used to 11.45 in 1884; to 52 in 1885, and in the first eight months of 1886, to 85 per 1,000.

Without wearying you with an immense amount of statistics, it may be of interest to state that for the past ten years the percentage of deaths from small-pox in the unvaccinated at the hospital in Boston has been 75, while of the vaccinated it has been only three. This, however, does not give a perfectly clear idea of the situation, for many of those who had been vaccinated did not have typical scars, and also in many instances the operation had been done a very long time previous to the attack of variola. There is no fatal case on record at the hospital in which vaccination was done within five years of the attack of the disease, except in those instances in which the patient was vaccinated at the time of exposure, and even then, if the operation was done within five days of the exposure the disease was always modified, to a remarkable degree.

The effect of one vaccination does not always last for a lifetime, and therefore the importance of re-vaccination is perfectly evident. For the ordinary exposure, in the routine of daily life, two or three vaccinations, at intervals of ten years, are sufficient; but after any extraordinary exposure a person should always be vaccinated.

In regard to the kind of virus to be used, I would say that my predilections are decidedly for animal lymph; because the protection is greater; because you can always be sure of an adequate supply for any emergency; because there is no danger of communicating syphilis. The possibility of communicating any other disease than this is so slight that no mention need be made of it. That certain eruptions do follow vaccination, and, owing to some inherent vice in the individual constitution are, in a measure, dependent on the operation no one with any experience will pretend to doubt; but these eruptions are acute in their nature and yield readily to treatment. A very common example of this condition is an eruption of urticaria following the ingestion of lobsters, or of strawberries, yet no one for a moment thinks of considering lobsters and strawberries unwholesome food. It is an interesting fact that young adults, and more particularly young immigrants, are liable to have these eruptions. In order to illustrate how frequently vaccination is unjustly blamed for the appearance of an eruption, I wish to relate the following case which occurred in my practice some few years ago. A perfectly healthy child, five months old, was vaccinated with fresh calf lymph; at the end of eight days the vesicle was perfectly typical in appearance and there was the usual amount of constitutional disturbance. At this time the mother of the child, who had never been vaccinated, expressed a wish to be vaccinated with lymph from the child's arm. This was done. At the end of four or five days the mother had a most extensive and general eruption of vaccinal urticaria with marked constitutional disturbance. If, in this case, the mother had not seen the lymph taken directly from her child's

arm no amount of argument would have convinced her or her friends, that the lymph was not impure. These vaccinal eruptions which are comparatively frequent, and which can be easily explained, serve as a never-failing source of argument against vaccination.

Let us now pass to the consideration of the measures to be adopted for the suppression of small-pox. In Boston, as soon as a case is reported, the patient is visited and the diagnosis verified. If the disease proves to be small-pox the patient, in suitable cases, is removed to the hospital with as many of the family as the circumstances seem to demand. The hospital is always ready to receive any number of patients. When the premises are vacated disinfection is immediately commenced. All persons in the vicinity, who have been exposed to the disease are vaccinated. There is a careful medical supervision of the infected locality until all danger of an outbreak of the disease has passed. Every inducement is offered for vaccination, which is free. The question of diagnosis is a very important one, and while it may be simple in a severe case, in a mild and modified form of the disease it is very often most difficult and perplexing. To give some idea of the difficulty of arriving at a positive diagnosis in these cases it is enough to say that during the past eight years there have been reported, to the Board of Health, as variola, about five hundred cases of eruptive disease of which only forty-four were found to be small-pox.

CHART A.

Deaths from Variola for Twenty Years—1862-71 and 1881-90.  
Deaths 521, p. 211,865. Deaths 25, p. 125,250.

In former years this disease was much more prevalent in Boston than it has been of late; but this comparative immunity cannot be explained by the wave theory of epidemics, and must, therefore, be due to the management of the outbreaks of small-pox that have occurred. Chart A represents the number of deaths from this disease, in Boston for two decades; 1862 to 1871, and 1881 to 1890, inclusive. The years of the great epidemic 1872 and 1873, have been purposely omitted; because, as this was an exceptional time, correct deductions could not be made from them. It can be seen at a glance that from 1862 to 1871, with a population of 211,865, Boston had 521 deaths from this disease, while from 1881 to 1890 inclusive, with

a population of 425,250 there were only 22 deaths. It is of interest to note that during the last decade immigration was very much larger than during the first. It must also be borne in mind that during the last ten years Baltimore, Philadelphia and Montreal have had moderately severe epidemics of this disease.

## SCARLATINA.

Satisfactory as the result has been in the suppression of small-pox there is no such favorable showing in the case of scarlet fever, although much has been done and with improved methods still more may be done. As this disease is pre-eminently one of childhood, it is evident that the removal to a hospital cannot be so easily accomplished as in the case of small-pox, which attacks the unvaccinated of all ages alike, and rarely, if ever, attacks a vaccinated child. The existence of mild cases of the disease in the community; cases that are not recognized, and therefore are not reported and in which there is no attempt at isolation, is one of the most potent factors in causing the prevalence of this disease. Notwithstanding the great amount of good done by the isolation of reported cases, to expect that this disease can be stamped out when in the schools and in the public conveyances, there are so many mild cases which serve as centres of ever widely-extending waves of infection, is to expect an impossibility. The difference of opinion among physicians regarding the time when a case ceases to be infectious, is also a source of great danger to the public. Children are frequently permitted, on the certificate of a physician to return to school, while they are passing through the stage of desquamation, and are therefore particularly liable to communicate the disease.

In Boston, a child living in a house where there has been a case of infectious disease, before he can return to school must bring a certificate from a physician stating that two weeks have elapsed since the death, removal or recovery of the last case reported. This regulation is a wise one so far as it goes; but, while the period of two weeks is long enough in the case of death or removal, the time of recovery is so vague and indefinite that it would be much better to require the lapse of six weeks from the commencement of the last case.

The isolation of a patient at his house is a difficult thing, but by the liberal use of disinfectants, and with the most careful and painstaking attention to detail, it can be accomplished, if the house is large enough and is occupied by only one family. In the ordinary tenement-house it is impossible.

The *British Medical Journal* of June 11, 1887, contains a paper entitled "Observations on a Method of Prophylaxis and an Investigation into the Nature of the Contagium of Scarlet Fever," by Drs. W. Allen Jamieson and Alexander Edington, in which are found some very important and interesting facts. Without quoting at length, it will be sufficient to give a few extracts:

"The method recommended was to disinfect the throat by painting it frequently with a strong solution of boracic acid in glycerine. In dealing with the skin more exact methods were available. These consisted in the employment of warm baths every night from the very first, and in the application to the entire surface of the body, including the head, of an ointment composed of thirty grains of carbolic acid,

ten grains of thymol, one drachm of vaseline, and one ounce of simple ointment. . . . Seven cases were selected; the baths and anointing were persevered in from the second day of the disease till the eighth day of desquamation, the seventeenth or eighteenth day of the disease. An ointment for inunction containing carbolic acid in the proportion of one in sixteen, had formerly been employed. Now and again slight evidences of absorption of carbolic acid had taken place, and, therefore, in these seven cases, an ointment of only one in thirty-two was made use of. On the eighth day of desquamation one leg was once more carefully anointed, enveloped in a thick layer of sterilized cotton-wool, bandaged and covered with a stocking, and allowed to remain undisturbed till the thirtieth day. The wool was then removed by Dr. Edington, with the same precautions as in the other cases, and the scales transferred to sterilized tubes for cultivation. It will be seen that the wool was put on at a period of the disease before the bacillus had been obtained from the scales, in cases where no disinfectants had been applied to the skin. This method subjected the procedure, therefore, to a rather severe test. In cultivations of scales from five of the seven cases no bacillus was found. In two it appeared in the cultivating medium; but, whereas, under ordinary circumstances the bacillary pellicle is formed in thirty-six hours it took six days to develop any evidence of its presence in the jelly. In five, therefore, the powers of reproduction of the bacillus had been checked, by the method adopted, while in the two others a remarkable retardation of the virus had resulted. We submit, therefore, that proof clinical and experimental, has been furnished that by such simple methods one can neutralize the contagiousness of scarlet fever, so far as that arises from the desquamating flakes of cuticle."

The importance of the facts brought out by these experiments is so great that the account of them has been quoted somewhat at length.

#### DIPHTHERIA.

The difficulties of dealing with an epidemic of scarlet fever, great as they may be, are much increased in the case of diphtheria. In the first place one attack of scarlet fever, in the majority of cases, protects a person from subsequent attacks; in diphtheria just the reverse is true; the first attack predisposes to a second. In the second place perplexing as the diagnosis may be in a mild case of scarlet fever, it is still more embarrassing in a mild case of diphtheria. In the third place the erroneous opinion that true croup and diphtheria are separate and distinct diseases and that important as isolation may be in the latter, it is unnecessary in the former renders the stamping out of this disease an impossibility.

The investigations of Klebs and Loeffler; and the confirmatory experiments of Roux and Yersin show conclusively that the diphtheritic germ is not absorbed by the healthy mucous membrane, and that the frequency of this disease during an attack of tonsillitis or during the course of scarlet fever and measles is due to this fact. In these experiments it was found that simply painting the mucous membrane of animals with the culture fluid was not sufficient to cause the disease, but if the mucous membrane was wounded by a platinum wire charged with the culture, diphtheria was invariably produced. This fact also explains to a certain extent the prevalence of this disease in New

England for it is apparent to the most casual observer that disease of the respiratory passages are more common here than elsewhere.

The degree of infectiousness of diphtheria has an important bearing on the subject of isolation. A very considerable amount of exposure is necessary to contract diphtheria and therefore a degree of isolation that would be useless in scarlet fever, would be effectual in diphtheria.

One very important measure for the suppression of these diseases is the disinfection of school-books, but advisable as this is there seems to be at present no safe and reliable method for accomplishing it. Sulphurous acid gas will not do this; heat, although it may kill the germs of disease, also destroys the books, and the same may be said of chlorine, and of a solution of corrosive sublimate. A series of very interesting experiments bearing on this point, was made some little time ago by two German observers, who found that, if the tips of the fingers were dry when turning leaves of books there was no deposit of microbes on them, but if the tips were wet with water or with the saliva a large deposit was found.

(To be continued.)

#### PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

BY HAROLD C. ERNST, M.D.,

*Instructor in Bacteriology at the Harvard Medical School.*

(Continued from No. 5, page 109.)

THE last division to which I shall call your attention is that of the miscellaneous cases, including those which have been under observation for too short a time to make any conclusions possible in regard to them, and three cases which presented themselves for treatment, and which were in such a condition that treatment was refused.

#### SECTION IV.

##### MISCELLANEOUS.—CASES XLIII—LII.

CASE 43. Boston. Admitted February 26, 1891. Service of Dr. John Homans. Born in Ireland, sixty-one years old, cook. Fair nutrition; good development and appetite. In June, 1889, underwent two operations for tuberculous affection of the knee-joint.

April 11th. Dose, .001 gm. Slight pain in knee, slight headache. No more than on other occasions.

April 13th. Dose, .002 gm. No reaction. Treatment omitted for the purposes of this paper.

CASE 44. Medford. Admitted March 4, 1891. Service of Dr. John Homans. Born in Massachusetts, eighteen years old, single, nurse. General health good; well developed; good strength, nutrition and appetite; heart and circulation negative; temperature 98°; pulse 100; respiration 20. Disease began one year ago, following a fall on the right knee. Had no inconvenience directly after the accident. A month and one-half ago the knee grew stiff; and a short time ago struck the knee again, since which time it has swelled much.

Examination shows good extension and flexion, almost normal; the knee is swollen over the patella, especially the quadriceps tendon; a little tender on the inside of the patella, which does not float.

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1891.

April 1st. Dose, .0012 gm. Back is sore; ice applied to knee.

April 6th. Dose, .0024 gm. Dizzy; increased pain in the knee.

April 11th. Dose, .003 gm. Headache; severe chills; treatment omitted.

*Summary.*—Number of injections, 3; amount used, 6.6 mg.; highest dose, 3 mg.; highest temperature, 103.4°, after the third injection of 3 mg.

April 28th. Knee in plaster splint. Improving. Discharged, not relieved (by treatment).

CASE 45. Hopedale. Admitted January 23, 1891. Service of Dr. C. B. Porter. Born in Rhode Island, nineteen years old, unmarried, painter. Family history negative. Disease began by a slip and fall one year ago. Examination shows the ankle much swollen, and also a swelling over the whole instep.

January 27th. Dose, .0012 gm. Pain increased in the ankle on the next day.

January 29th. Dose, .0024 gm. Pain still increased.

January 31st. Dose, .0036 gm. Pain increased during the afternoon and the next day. The ankle is placed in a stiff bandage. Discharged by Dr. Porter, to use cod-liver oil for a time.

*Summary.*—Number of injections, 3; amount used, 7.2 mg.; highest dose, 3.6 mg. (Chart lost, so no record of temperature attainable.)

CASE 46. East Boston. Admitted January 23, 1891. Service of Dr. E. H. Bradford. Spinal caries with abscess. The trouble dates back about a year. There is an abscess in the left iliac fossa, the size of an orange.

January 24th. Operation. Six ounces of pus evacuated.

February 21st. Dose, .0004 gm.; 22d, .0008 gm.; 24th, .0009 gm.; 25th, .0012 gm.; 28th, .0015 gm.; March 2d, .0018 gm.

March 4th. Dose, .0024 gm. Scarlet fever broke out in the ward, and the patient was discharged.

*Summary.*—Number of injections, 7; amount used, 9.1 mg.; highest dose, 2.1 mg.; highest temperature, 101.1°, after the fifth injection of 1.5 mg.

CASE 47. South Boston. Admitted February 10, 1891. Service of Dr. E. H. Bradford. Born in Boston, six years old. Mother died of phthisis. General health poor; anemic; poor strength, nutrition, appetite and sleep; heart and circulation negative. Disease began with pneumonia, in December, 1890. Pus was found in the chest on February 8th, by aspiration. Signs of the fluid throughout the front of the left chest. February 10, 1891, a pint and one-half of thin pus was evacuated.

February 20th. Dose, .0004 gm. General condition fair; appetite fair.

February 22d. Dose, .0008 gm.; 28th, .0009 gm.

Upon March 3d, the mother was dying of phthisis, and, therefore, the patient was discharged.

*Summary.*—Number of injections, 3; amount used, 2.1 mg.; highest dose, .9 mg.; highest temperature, 101°, after the third injection of .9 mg.

CASE 48. Boston. Admitted January 23, 1891. Service of Dr. E. H. Bradford. Born in Boston, five years old. Disease began eight weeks ago, in hip. Operation performed on January 29th, and two pints of pus were evacuated.

February 20th. Dose, .0002 gm.; 22d, .0008 gm.; 24th, .0009 gm.; 26th, .0012 gm.

Gained constantly while the treatment was going on. Scarlet fever in the ward, and so was discharged.

*Summary.*—Number of injections, 4; amount used 3.1 mg.; highest dose, 1.2 mg.; highest temperature, 101.4°, after the first injection of .2 mg.

CASE 49. South Boston. Admitted February 17, 1891. Service of Dr. Bolles. Born in East Boston, seventeen years old, single, nursery-maid. Well developed; good strength, nutrition, appetite, and sleep; heart and circulation negative; urine, pale, neutral, 1008, no albumen; abdomen negative.

February 20th. Section of tendon of peroneus longus removed (the second operation) for four inches. The report from the old operation is a diagnosis of "tubercular teno-synovitis."

March 13th. The incision wholly healed except one inch in the centre, one-half inch wide. Red, healthy granulation.

March 24th. Lungs normal. Incision almost entirely healed. Granulating area the size of a one-cent piece. Discharge slight; no pain in the foot. Has grown fat since entrance.

March 27th. Urine normal, acid, 1020, no albumen.

March 28th. Dose, .001 gm. Bacilli from discharge, 0. Urine normal, acid, 1022, no albumen, calcic-oxalate crystals.

April 12th. Dose, .01 gm. Treatment omitted for the purposes of this paper.

*Summary.*—Number of injections, 7; amount used, 40.3 mg.; highest dose, 10 mg.; highest temperature, 103°, after the fifth injection of ten milligrammes.

CASE 50. Marion. Admitted March 1, 1891. Service of Dr. Forster. Born in Martha's Vineyard, forty-seven years old, married, physician. Family history of tuberculosis on both sides. Diphtheria in 1873; slight pneumonia in 1888, with a severe cough. Has had a cough ever since the attack of diphtheria. General health fair; hæmorrhage once; well developed; fair strength; emaciated; fair appetite and sleep; heart and circulation negative; no night sweats; temperature 97.9°; pulse 96; respiration 24; breathing easy; has a slight cough in the morning; slight expectoration; voice has been affected for two years; slight pain in the chest.

Physical examination shows dulness, with increased vocal resonance, broncho-vesicular breathing, and numerous fine and coarse moist râles over the whole right front; over the left front, dull, broncho-vesicular breathing, increased vocal resonance, with râles down to the third rib. In the back, on the right, the same signs of consolidation as in front; on the left back, the dulness, etc., goes just below the spine of the scapula. Over the lower lobe of the left lung, front and back, breathing is fairly normal, with only a few moist and dry râles. Could get no evidence of cavities in the lungs.

March 3d. Sputum bacilli, No. 9. Treatment refused.

CASE 51. Boston. Admitted March 3, 1891. Service of Dr. E. H. Bradford. Born in St. John, N. B., twenty-three years old, married, housewife. Mother, brother and sister died of phthisis. Mother's family consumptive. Never sick except present illness. Disease began with a cough, sixteen months ago. Menses have been scanty for the past few months. No hæmorrhages; slight loss of weight; well developed and anæmic; fair strength, nutrition and appetite; heart enlarged to the left; lungs normal; has had night sweats

for three or four weeks; temperature  $102^{\circ}$ ; pulse 132; respiration 26; dyspnoea; is very hoarse; has considerable cough; thick and frothy expectoration, and a good deal of it; often vomits after breakfast. Urine normal, acid, 1019, a distinct trace of albumen, uric acid increased; it contained considerable sediment and many uric acid crystals; also hyaline, fine, granular, waxy casts, a little fat on the casts, and a few fatty round cells.

Physical examination shows dullness and bronchial breathing at the right apex, front and back; numerous fine, moist and medium râles, over both front and back, as low as the angles of the scapulae. A few dry râles also over these areas.

March 6th. The morning temperature was normal, but in the evening ran from  $101^{\circ}$  to  $102^{\circ}$ .

March 8th. Treatment refused.

March 9th. Bacilli in the sputum, No. 6.

Case 52. Boston. Admitted January 29, 1891. Service of Drs. Mason and Rotch. Born in Virginia, twenty-two years old, waiter. Family history negative. Had gonorrhoea and chancroids several times, and influenza in the winter of 1889 and 1890. The disease began in August, 1890, after a severe run, having a hæmorrhage then; and this was followed by a severe hæmorrhage the next week. Temperature  $99.6^{\circ}$ ; pulse 92; respiration 25; considerable laryngeal cough, which interferes with sleep; slight sero-purulent expectoration. Bacilli have been found in the sputum. Urine negative. Has had no trouble since August until seven weeks ago; then he took cold, and had a sore throat; has been very hoarse, lost his voice four weeks ago.

Examination shows dullness at the right apex, and numerous medium, moist râles; broncho-vesicular respiration under the clavicles at the outer part, front and back; lower middle portion shows sibilant râles; prolonged expiration and a few moist râles; no dullness on the left, though there are some râles.

January 31st. Dr. De Blois diagnosed catarrhal laryngitis and thickened epiglottis.

February 23d. Temperature  $100.5^{\circ}$  to  $102.5^{\circ}$ . Treatment refused.

March 19th. Discharged worse.

Cases 43 and 44 (both affections of the knee, the first with a sinus) and the second without, were treated for too short a time for any judgment to be passed upon them. Case 43 showed no reaction, either general or local; while Case 44 had a very sharp rise in temperature and a marked disturbance of the general condition, as well as increased pain and swelling of the knee. The latter, however, may very readily have had nothing to do with the injections.

Case 45 (disease of ankle) was discharged by the attending surgeon before any change or conclusion could have been reached.

Cases 46, 47, 48 (all disease of the hip, and all in the Children's Hospital) were all discharged before any prolonged treatment had been given them, for the reason that scarlet fever broke out in the ward, and the parents took the patients home. One or two of them showed a gain in general condition before this occurred, however.

Case 49 (teno-synovitis) was discharged from the treatment soon after it was begun, for the reason that, in order to gain time for making this summary, I was obliged to stop all hospital work temporarily.

Cases 50, 51 and 52 (all of pulmonary tuberculosis, and all with many bacilli in the sputum) were rejected for treatment, because the disease seemed to be too far advanced, or the strength of the patient was much weakened. The histories will be published in full with the rest; and it seemed to be proper to give a selection of such cases for the possible guidance of others.

The use of Gaffky's tables for the classification of specimens of sputum containing bacilli<sup>6</sup> has made it possible to make out certain curves that it will be of interest to show. Taking the absence of bacilli as representing 0, and then going on with his enumeration, we can build up a series of transverse lines running to ten. The lateral space is devoted to the dates of the examinations, each space being separated by a perpendicular line. Then dots placed high or low, as the case may be, represent the number of the bacilli, and when connected, give a very graphic representation of the variations of their appearance in the sputum.

Charts of this kind have been worked out very thoroughly for me by Mr. A. D. Hodges, a second-year student in the medical school.

A chart from the sputum examinations of Case 1 (pulmonary tuberculosis) shows a constant persistence of the bacilli, and their presence in pretty large numbers. A chart from Case 2 (pulmonary, laryngeal, and probably abdominal tuberculosis) shows first a high curve,—a marked diminution that apparently corresponds with the temporary improvement that was manifest in this case,—and then again a sharp rise. A chart from Case 3 (pulmonary) shows a general rise in the curve. A chart from Case 4 (pulmonary, and tuberculous scrofuloderma of the neck) shows a constant low average in the sputum, most of the time they being absent. A chart from Case 6 (pulmonary) shows a constant and marked rise from about the middle of the treatment, the last examination giving them in enormous numbers. A chart from Case 8 (pulmonary) shows two periods of rise and decline, the last leaving it higher, however, than at the beginning of the examinations. A chart from Case 9 (pulmonary) shows also a period of increase after the treatment was begun; then a fall, and a second rise, that up to the time of the last examination had not gone so far as did the first one. A chart from Case 11 (pulmonary, and of knee) shows a very remarkable and persistent fall after the first of the treatment. A chart from Case 17 (supposed pulmonary tuberculosis) never showed any bacilli. A chart from the sputum of Case 25 (tuberculosis of tongue and lung) shows a constant climb, highest at the last examination, and lowest at the times of the apparent improvement of the patient. A chart from the secretion from the tongue of Case 25 shows always a low average, but seemingly lowest at the times of apparent improvement in the lesion of the tongue.

The charts from Cases 11 and 12 are so remarkable that, although by themselves they show nothing, it seemed to be a matter of importance to find out whether anything similar would occur in the ordinary course of the disease as it advances, or exists under ordinary treatment. Fortunately the means for this

<sup>6</sup> Mitt., n. d. Kais. Gesundheits, Bd. 11, 1883.

comparison were easily at hand in two ways. The first was from some work of my own, embodied in a paper read before the Massachusetts Medical Society in June, 1883; for the purposes of which I had made a similar series of examinations and charts. These charts are five in number. They represent the results of examinations extending over about three months at the same season of the year as the first series; are classified in a similar manner; and show *exactly the opposite* of what is seen in the new charts of Cases No. 11 and 12, that is to say, that there is a *very evident* rise of the curve as the time of the examinations extended. The second means for comparison is with work not done under my direction or by me, namely, in the results of the sputum examinations given by Gaffky in the same place as cited above. A series of examinations is there recorded of the daily number of the bacilli in the sputum; and when they are plotted out, the curves show the same point as do those made by myself, — a constant and steady rise as the disease progresses, or at least a holding of the same level, with never but once a drop at all like that shown in charts of Cases 11 and 12. This one drop being in a case that died shortly after the examinations were begun, but in which there had been a constant and steady improvement in the condition of the patient, death occurring from peritonitis after swallowing about sixteen or eighteen prune stones. The conclusions that may be drawn from these facts are, of course, not final; but the facts are certainly of interest, and possibly of great importance.

I hope that I have so reported the cases, that it will not be necessary for me to state that, in many of them, at least a part of the improvement noted has been due to the more favorable surroundings of hospital life and care; but to make the matter certain, I wish to say plainly, that in all cases this influence has been fully considered and given due credit in making up the results. In some of those marked as relieved, this influence has undoubtedly played a marked part — exactly how much, it has seemed to me better to leave to each one to judge for himself, as it will not be difficult to do when the full records of the cases are published. But with all that excluded, there are some effects that have been seen that are unexplainable to my mind by this beneficial influence alone.

My experience with tuberculin, has apparently corresponded with that of most others, and with what I saw in Berlin. There is a marked and rapid improvement in certain cases, more especially those of external tuberculosis (including lupus), which goes on for a certain time and then stops, and the effect of the material is lost. The cases even begin to retrograde. Seen at a certain time after the treatment has been going on, the results for the future are very apt to be gauged by what has been accomplished in the first of the treatment; and this is precisely what happened in my observations in Berlin. I saw there the same — only more marked — improvement in cases of lupus, pulmonary tuberculosis, and surgical disease, that has occurred in certain of the cases here; but neither there nor here has the early promise been kept up.

The question then arises, How much real good does this material accomplish, and how far is its present form the one to use, if any good be accomplished by it?

Of the treatments in regard to the material, the most interesting that I have seen, are those made by

Arloing,<sup>6</sup> in which he says that he has been unable to secure immunity to tuberculous inoculation in guinea-pigs, — as did Koch; and he suggests an extremely important point, that deserves most careful consideration. He thinks it possible that cultures of the bacilli of tuberculosis become more or less attenuated in their growth — when this covers a prolonged period of time — and that possibly the apparent immunity of the animals experimented upon was due to the fact that the cultures used to test this immunity were *attenuated* in their virulence. That cultures of bacilli of tuberculosis *may* lose some of their virulence after long cultivation, and under varying circumstances that may be not intentional, seems to be undoubted. Arloing goes on to the conclusions, or rather suggestions, that the differences seen in the effect of tuberculin in the different classes of cases may be due to the fact that the bacilli concerned in the production of these different classes may be possessed of varying degrees of virulence, and may therefore be influenced in a varying degree by the material.

For example, he suggests that the bacilli of lupus and surgical tuberculosis may be of a less intensity of virulence than those in advanced cases of pulmonary disease or in acute miliary tuberculosis; and hence the cases of marked improvement reported in the first category, and the absence of them in the latter.

Kast,<sup>7</sup> of Hamburg, says — what is very true — that thus far we are not certain of the dose that we are giving of this material; and that, until the toxalbumin is separated and fully studied, it will be impossible to get at its exact action. As is well known, tuberculin does not pretend to be a pure material. There is estimated to be but one per cent. of the active ingredient in the flasks, as put upon the market; and it is quite possible that this amount may vary very considerably in the course of manufacture. It is unfortunate, to the last degree, that it was put upon sale, or distributed at all, before this point had been thoroughly worked out; but, at the same time, to those who are really responsible for the action should be given what criticism is due, and this judgment should be made very carefully.

M. and Ad. Jolles<sup>8</sup> have given a preliminary chemical analysis of "kochin," that may be of interest. They find fifty per cent. of water; absence of any traces of cyanogen or alkaloïds; a strong albumenoid reaction; absorption band at the boundary of the green and violet fields between b and F, the absorption spectrum therefore agreeing with that of urobilin. The albuminate is precipitated with tannic acid, as a white voluminous precipitate, which is soluble in hot water, salt solution, and very dilute liquor potassae. The elementary analysis and nitrogen determination give: N. 5.90 per cent., C. 35.19 per cent., and H. 7.02 per cent. From the results reached, therefore, the active principle of tuberculin is a toxalbumin.

In the *Boston Medical and Surgical Journal* of May 7, 1891, (page 167), there is an editorial speaking of the discussion before the German Medical Congress at Wiesbaden in April. A large number of clinicians took part in the discussion; and the editorial mentions the most important statements made. It is interesting to find that even now, so good a clinician as V. Jaksch, of Prague, feels that there is a diagnostic

<sup>6</sup> Rev. de Med., February 10, 1891.

<sup>7</sup> Dent. Med. Week., No. 17, 1891, p. 610.

<sup>8</sup> Ver. Klin. Rundschau, v, No. 1, p. 10, 1891.

value to be attached to tuberculin. He says: "It cannot be doubted that the discovery of Koch is of high diagnostic value; also, all my colleagues agree with me, that, by Koch's observations, therapeutics are led into a new, and, as it appears, a fruitful route." He goes on to say that the therapeutic results have not borne out the high hopes he had had, but — "and this I must lay stress upon, it is probable that four months is too short a time in which to make a final judgment in the matter."<sup>9</sup> The JOURNAL editorial closes in this way: "We sympathize as little now with those who are anxious to have the whole treatment thrown aside as utterly worthless, as we did previously with the ultra-enthusiasts who predicted that tuberculosis was soon to be a thing of the past."

Certainly no accurate knowledge of its action upon tuberculosis, as a whole, can be gained, except by the careful collation of statistics; and these statistics must have for their basis work thoroughly carried out in all the necessary branches of the investigation, with plenty of force to do it.

#### THE OTTAWA HOSPITAL OF THE SANTA FE RAILWAY EMPLOYEES' ASSOCIATION.

BY GEORGE W. NASH, M.D. (HARV.), OTTAWA, KAN.

THIS railroad hospital is situated in Ottawa, Kan., on a branch of the Atchison, Topeka and Santa Fé Railroad, fifty-eight miles south-west of Kansas City, and is one of the newer hospitals belonging to the Association. Being situated at a junction point, and readily accessible to all the larger points on the line, the location is an admirable one. Patients come from the Santa Fé Territory immediately contiguous, in Missouri, Kansas and the Indian Territory; in addition also, under the system of transferring patients from one hospital to another, the hospital has had men from almost every portion of the Santa Fé system, — Iowa, Illinois, Texas, Colorado and California all having furnished patients. This transferring of patients is an excellent feature in the Association, as out of the number of hospitals, climatic conditions may be found for about every case. Patients are admitted for care and treatment for disease as well as accident, the Association guaranteeing this in accordance with the plan of assessment. Since the opening of the hospital, June 1, 1889, up to date (April 20, 1891), there have been admitted 520 patients, the average being here about two medical cases to one surgical case. The medical cases under treatment are mostly acute troubles, although chronic diseases, as consumption, rheumatism and the like, are not excluded; of medical cases, typhoid fever claims by far the larger number. The surgical cases are of various kinds, and mostly due to the nature of the occupation of the patients, whether in the shops as day laborer or in train service.

There have been eleven deaths: one from septicæmia due to extensive laceration of the knee-joint (no operation allowed); one from shock and exhaustion, due to very extensive laceration of entire arm (no operation allowed); one from syphilis; one from pyo-pneumothorax; one gastric cancer; one from rheumatism; four from typhoid fever; and one from peritonitis.

When the nature and condition of the patients is taken into consideration, consisting of all classes and

nationalities and representing all classes of employees, some being constantly exposed even in inclement weather, we think the mortality record is a very favorable one. For burial purposes the Association allows a certain ample sum for the proper and decent burial of the employee; and the friends, if they wish more elaborate furnishings, make up the balance.

The patients are received on the recommendation of the local surgeon first treating the case, and on their arrival are given a bath, the exception to this being seldom found. Hospital clothing is furnished by the Association, and, in addition, for those who need them, undershirts, drawers, socks, overalls, flannel coats and slippers are provided. As soon as a patient is admitted and the diagnosis made, his name is put on the diet list under its proper heading: "fever, sick, house diet, and house diet in bed" being those understood. A duplicate list is kept in the kitchen, so that an exact carrying out of orders is secured. The different diets are self explanatory, although a few words may be said about them. Fever diet consists invariably of milk, egg-nog, beef tea and broths, and some of the different food preparations, as milk powder, Nestle's food, and the like; sick diet includes, in addition, at meal times, soft boiled egg, dropped egg on toast, dry toast, chicken and bread and butter, although the matron exercises discretionary power in each individual case, on consultation with the surgeon. These two diets have special times, 7 and 10 A. M., 12 M., 2, 4, 6 and 8 P. M. Naturally, in special cases, special times for giving nourishment are ordered. No rations are issued, each patient having all he may desire of the dietary ordered for him.

A bath-room is furnished specially for patients, and can be used at any and all times, no restriction as to its use existing. Patients' clothing is laundered for them in the hospital laundry; and at their departure care is taken that the patients are not obliged to carry any soiled clothing away with them. A Chinaman is employed, and it is found that he can manage all the washing needed in the hospital: ward and patients' clothing are washed on Monday, and returned Tuesday ready for use; house clothing and that belonging to the hospital employees are washed Wednesday, being delivered Friday. The laundry being fitted with a good dryer, drying the clothes can always be done in stormy weather, although sun and air drying is insisted upon as far as possible.

The care and cleanliness of the building is scrupulously maintained. The wash-room, water-closets, patients' sitting-room, and all halls are carefully cleaned daily; the ward floors are carefully cleaned with soap and water every alternate day, and carefully swept the intermediate days. To avoid unnecessary dust in the daily sweeping, parlor brooms are used, a soft damp cloth being pined over the brush; in this way the sweeping is done with absolutely no dust. Dusting is also done with damp cloths, wiping being a more accurate term, feather dusters being tabooed as abominations. Beds, woodwork, chairs, tables and the more inaccessible parts of the rooms, are cleaned with soap and water, weekly. In addition, once a year all the walls are carefully scrubbed with plenty of soap and water, with a liberal addition of carbolic acid or corrosive sublimate. Good ventilation is continually maintained, fresh air always entering the wards, — through open windows in summer, and in winter through ventilators over hot pipes. If a man feels chilly, put on

<sup>9</sup> Von Jaksch: Deutsch. Med. Woch., April 16, 1891, p. 583.

more blankets, and not rush to close every ingress of fresh air, being the rule and observance. All litter, sweepings, lint and dressings are burned up in the boiler fires, as fast as gathered. The ward tables are kept as neat and tidy as possible, being simply used for what necessary articles a patient must have, and are not catch-alls for food, fruit, medicine bottles (which have a special closet), articles of clothing, and what not.

There are ten employees all told, as follows: Surgeon. Matron, who has charge of the housekeeping, and also has an oversight in the care of the patients. Houseman or orderly, who does the daily heavy cleaning in winter, he takes care of the boilers during the day, and in summer cleans the numberless windows. Male nurse, whose duty varies; he sleeps in a small room adjoining the wards, ready for call by electric bell from the patients, or from an arriving patient, and in winters keeps up the fires during the night. If any case needs special attention, or when there is a run of sickness, he remains up all night, getting needed rest during the day in another part of the house. In the morning, if not thus busy, he empties spit-cups and urinals, throws back the bedding in use, and helps the patients dress. The care of the patient's wounds and injuries is done as early in the morning as possible, and he assists the surgeon in this as well as in his operations. During the day, he is ready to help in care of patients, as may be needed, and has always found time to maintain a nice vegetable garden. Two women nurses are employed, who go on duty at 5.30 A. M., and whose work ends when the patient's supper dishes are cleaned. They have two hours for change and recreation every alternate day. They sweep and prepare the wards and rooms for the houseman, dust rooms, and make the patient's beds. They have the care of the inmates all the time they are on duty. In addition a cook, kitchen-girl, chamber-maid and laundry-man are employed.

The hospital itself is on the cottage plan, consisting of the ward building and administration building, both connected by a corridor. The ward building is long, and has but one story, containing two large wards with a hall between, each having twenty beds. Between these wards, on one side of the hall, are a small ward of three beds, a baggage-room, a dining-room for patient, which is also a sitting-room; on the other side of the hall are a bath room, wash-room and water-closets, entrance from administration building, and nurse's room, with pantry. There is an outside door from the dining-room, by which patients may go in and out. The baggage-room is for storing patient's clothing, having as many stalls as there are beds, and numbered to correspond, so each man may easily know where his own clothing is. This room is constantly kept cleaned and ventilated, and thoroughly fumigated with sulphur yearly. Besides the overhead ventilation, and that secured by windows and transoms, there is a ventilator under each bed, connecting with the main chimney.

The administration building is two stories and a half high, containing operating room, apothecary office and dining room and the necessary store and sleeping rooms for the hospital employees.

There are even acres of ground belonging to the hospital, with apple orchard and vegetable garden; benches are put around in convenient places for lounging and shade.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, Monday, May 11, 1891, the President, DR. FREDERICK I. KNIGHT, in the chair.

DR. H. C. ERNST read a paper entitled

#### PRELIMINARY REPORT ON THE CLINICAL USE OF TUBERCULIN.<sup>1</sup>

DR. E. H. BRADFORD: Of course, I can only give general impressions in regard to these cases, because I have left the matter of record and inoculation entirely to Dr. Ernst; and, as we know, Virchow has said that there is nothing so fallacious as the general impressions of medical men. I shall therefore be very scant with my general impressions. There were but two cases that I referred to Dr. Ernst where I could state that improvement followed, I mean improvement in the clinical sense. The one was a case of excision of the wrist which I did. The case did well after the excision, a slight sinus being left, however. I etherized him to curette the sinus, and also to remove the portion of the radius which had not been removed during the excision. It was removed as it was diseased, and on the recovery there was a deformity left. At the second operation I was enabled to examine the tissues very carefully, and I must frankly confess that it seemed to be thoroughly free from any granulation tissue or œdema such as one often sees from excision of tubercular tissue.

The other case is the one referred to by Dr. Ernst, where the patient has made a noticeable improvement in the general condition. I am inclined to think that the improvement may be due to the tuberculin, though I am not positive as to the matter, because the hip disease was not of a very severe form. In his statement he notes that the patient is now walking about with crutches. I think that should be amended, for the patient received permission to walk about with crutches at the time treatment was undertaken. The patient has improved markedly, however, in general condition since the injection of the tuberculin, and the ulceration of the cornea which had not yielded, has yielded entirely under this treatment, whether for that reason, or otherwise, I don't know.

In regard to the other cases I should state that there had been no marked change.

DR. BOLLES: Of the cases Dr. Ernst reported, four were more or less under my care. They were all of them peculiar cases and interesting on that account. One of them, a case of tuberculous disease of the joint had been operated on some months previously, and I think persistent sinuses had remained, sometimes one and sometimes two. This condition had been going on for three or four months without any perceptible change, when Dr. Ernst undertook the Koch treatment with him. During the continuance of that treatment the patient had very marked, and, I believe, typical reactions. The physical discomfort was greater than that of the others. The patient looked during the several weeks of treatment, if anything, more poorly than before it. The condition of the knee-joint was unchanged, excepting after the first and second injections there was a certain amount of increase of turbid fluid, and

<sup>1</sup> See page 6 of the Journal.

after that I could not see any effect on the knee-joint by the injections, but the man did have pain in the small glands of the neck and pains running up and down the affected leg. After some weeks of treatment it was discontinued, and since then I understand his improvement was unusually rapid. That may look as if the treatment had had a retrograding influence upon him. I do not think that was the case, because up to the time of the treatment he had been stationary practically for weeks, and remained so during the treatment, and afterwards got well quite rapidly, and has gone about on crutches.

Another case was one with a questionable growth at the head of the fibula. The operation was done as a means of assisting diagnosis between tuberculosis, syphilis and sarcoma. It was a very ill-defined growth, and the history was very imperfect. This patient had, I believe, no reaction whatever, but did have an attack of pneumonia within one or two weeks of the first injection, and was treated for that and recovered and was returned to the surgical side of the hospital after I left duty. I inquired for him a few days ago, and found that the leg had been amputated, and that the tumor had proved to be sarcoma.

The two cases of pseudo-leukamia were more or less under my care, and in them I was very much interested because I have always had a suspicion that there was a sort of relationship between pseudo-leukamia and tuberculosis, and was very anxious that these cases should be tested with that in view. Dr. Ernst has given the result of them. One died afterwards in which there was no benefit during the treatment where the patient had a marked reaction, and Dr. Ernst reports finding once some bacilli in the sputum. He did not mention that in the course of this febrile reaction there was no evidence whatever of any reaction in the glands themselves. They were not, as I recollect, increased in size, showing that they were not, perhaps, concerned in the condition of tuberculosis which was partly proved by the reaction and by the discovery of bacilli. He died of pneumonia complicated by pleurisy.

The fourth case, where there has been marked diminution of the glands after treatment was discontinued, is very remarkable, and is at present too recent to form any conclusions in regard to it. The patient has had similar histories before, although not so marked as this present one. He had enlarged glands in the neck which, after continuing for some months and after the febrile reaction, did diminish very much and nearly disappeared in the way those of the chest have done, but I understand the glands were not as large as the chest glands were, and the diminution not so sudden and marked. The patient himself considered this a very remarkable subsidence. He is one of those cases who has always had paroxysms of fever coming on once in three or four months for the last few years. I think we shall have to watch him some months longer before deciding how much influence the treatment had.

Of the cases Dr. Ernst has reported two have died of pneumonia, that is two out of forty-eight or forty-nine, and these were cases also that were in the hospital, and those that were not cases of tuberculosis of the lung were not supposed to be particularly liable to pneumonia. Perhaps Dr. Ernst would state a little more definitely whether he considers the advent of pneumonia a possible complication of the treatment or

whether he considers that it was entirely independent of it. Unless I misunderstood him, some of the cases which died following the treatment in Berlin, and he read the report from Virchow, died from pneumonia in one form or another. Is there a danger in using this method of treatment that we may bring on an attack of pneumonia of some form in our patients as a result of it? This Italian, who had sarcoma, had been in bed in the hospital two or three weeks, and there seemed to be no reason why he should be taken down with pneumonia. The other man was sitting up and about, and was a weakly subject, and bacilli had been discovered in his sputum, and that was not so remarkable, but the Italian seemed to have no reason for pneumonia.

Dr. J. C. WARREN: I shall not attempt to go into detail in regard to the cases which I had, but merely state my general impressions. The cases which I had varied greatly in their general characteristics. One was a case of lupus of the most typical character. I shall not have much to say about that case. Dr. White will speak with more authority about it. I will merely say this, that at first there was a very marked improvement. Everybody felt very enthusiastic about it. I have not followed the later history. I understand there has been a return.

One case I have followed pretty carefully from the beginning. That was a case of lupus of the tongue. It was an undoubted case of tuberculosis, because I removed a specimen which was examined microscopically by Dr. Whitney, and was a most typical specimen of tubercle. It seemed to me a particularly favorable case for study, because there were no crusts or scabs, and yet it could be examined, and one could see exactly in what condition it was in the beginning. At first, there seemed a certain amount of improvement. Certainly I was very much disappointed in the general reaction which I expected to see from the cases which were reported in Berlin. I expected to see that tongue swell up, and great exudation take place, etc.; I did not see that. There was a gradual healing of the ulcer so that it nearly all healed, but at the present time the nodule is larger than it was before and the ulcer is two or three times as large as it was before and is decidedly worse. The general condition of the patient, however, seems to me to improve very decidedly.

Some of the other cases I see on the list I do not consider proved much one way or the other; for instance, that case of sinus in the chest where after trying a little while the injections I decided to resect the rib, and see what there was, and found a drainage-tube which had been put in at some previous time. I understand Dr. Ernst has said it has improved very much since then.

Another case was a case of syphilis which was not practically treated, because it was found not to be tuberculous, and has improved very greatly under iodides.

Another case was tuberculosis of the bone; and I think we ought to remember this fact, that tuberculosis of the bone where there are sinuses is a mixed infection. We have bacteriologically the tubercle bacillus and the pyogenic cocci, and we may hammer away all we please at the tubercle bacilli and we shall still have that suppurating joint the same even if we clean out every bacillus there is there. The bone is disorganized. You can't make new bone with any remedy

we know, and we can only clear away the wreck there is there by a surgical operation; therefore, it seems to me, that those cases of bone tuberculosis which are brought forward as experiments are not particularly suited for that kind of work. More suitable perhaps are the cases of tuberculosis of the lymphatic glands. The only case of that class was the case of the young woman who went home to die, where the disease was altogether too advanced to make a proper test. She had been under my care and that of Dr. Richardson a year before, and we had done two or three operations. After the treatment was begun there was found extensive internal tuberculosis.

Although that in a general way has been the result of my personal observation, I must say I would like to take this opportunity to raise my voice in protest against the undue reaction of feeling, which, it seems to me, has taken place against these experiments. I remember very well coming home from Europe about the time the antiseptic treatment was started. When I reached London I heard for the first time of Lister and his method of treatment. I came home in the course of the summer fully supplied with all the materials, which I procured from Lister himself who was at Glasgow; and when I arrived and informed some of the senior surgeons that I had the materials and was ready to undertake experiments, I was rather snubbed. They said: "O, we have tried and abandoned this carbolic treatment." We know how long it took for the antiseptic treatment to be introduced here. It was ten years after Lister first advanced it before it was accepted in Boston as the mode of treating wounds. I recently read over one of the clinical lectures written by Bergmann, who first performed these injections in Berlin, and was perhaps the most prominent figure amongst the people there in the carrying out of the treatment. His paper has for its title the treatment of lupus, and he has no cure to offer. His report is what we all know: at first improvement, and then return. His observations are interesting, it seems to me, because he had made microscopical examinations in given cases from time to time of the tissues, cutting out pieces and examining them to see the condition in the interstitial tissue and the tubercles themselves; and the effect of this treatment seemed to him to be like that of an acute inflammation supervening on a chronic inflammation or chronic ulcer. That is the familiar action of erysipelas on an old ulcer. It appeared to affect the tissue rather than any specific structures that existed there. Miliary tubercles were not affected at all, but the surrounding granulation tissue was congested, filled with exudation and at times gangrenous. I have seen nothing of those very intense reactions, and the reason appears to be this, that in reading over the accounts of his treatment very much larger doses seem to have been used in Berlin than here. Of course, the gentlemen who first started the treatment in this vicinity were anxious to be cautious and not produce any bad results, which was proper; but it seems to me that owing to that we have not had the results which they have got in Berlin. We have not seen any of those great swellings, sloughing out of sinuses or ulcers or infiltrated masses. I see that they give, not four or five milligrammes, but ten, fifty, five hundred, a whole gramme, two grammes at times in Berlin, and in that way they must get very much more marked results.

Dr. L. M. ROCHER: A case of great interest to me

was No. 12. This patient showed a decided diminution in the number of tubercle bacilli, but the physical examination of the lungs, which I made just before he left the hospital, showed that the disease had progressed rather than diminished, and that, although he had gained six pounds, he seemed to me very much like a large number of others who improve under various treatments while in the hospital. He did not seem to have made any great gain, and clinically was worse rather than better. The case was interesting as showing the discrepancies which may arise between the clinical aspect of a case and the bacteriological.

No. 32, the case of pseudo-leukemia, was also of importance, and will perhaps be spoken of more fully by Dr. Mason. It came under my care on February 1st, when I took charge of the ward, and at that time I supposed it was a case of tuberculosis. The chart showed the decided reaction of tuberculosis, and the injection treatment was carried out with that view. The man began to lose and to grow worse, and requested that the injections should be stopped, which, with Dr. Ernst's approval, was immediately done. Within a very short time his temperature went up and he developed the physical signs of pneumonia in the left lower back. The man died, and then the question was whether it was a case of tuberculosis or not. Dr. Gannett performed the autopsy, and the pathological diagnosis was pseudo-leukemia and pneumonia. The bacteriological records of Dr. Jackson were, that in the first examination no bacilli were found, in the second none, in the third one bacillus was found, and in the fourth examination none. The case seems to throw doubt on the value of the temperature curve as a means of diagnosis in tuberculosis.

Case 11 I examined, and found no better and no worse.

Dr. F. C. SHATTUCK: There is only one of these cases about which I shall say anything, Case 9, a private patient of mine, with limited pulmonary tuberculosis, who had improved decidedly under general treatment. He received the Koch treatment because he demanded it. I told him I did not advise it, but that he could have it if he wished. Throughout his stay in the hospital he was in my ward, and I could see no improvement in his general condition. The sputum lessened in amount, though the number of bacilli does not seem to have diminished. He said he felt better, and could laugh, which he was unable to do before undergoing the treatment. There was no gain in weight to speak of, and the physical signs increased in area.

The cases in which I felt special interest were those of cutaneous tuberculosis, in that they afforded the best opportunity of studying the effect of the tuberculin. These cases were furnished by Dr. White, and I am sure that you would rather hear his opinion of their progress than mine.

A number of people applied to me for the treatment, to whom I either absolutely refused to give it, or whom I advised to wait until we should know more about it.

Dr. Warren alludes to the tardiness of the profession in Boston in adopting Listerism, and seems to draw a parallel between that tardiness and the present feeling with regard to tuberculin. There were reasons peculiar to Boston, I think, for the slight degree of favor with which Listerism was originally received here. In this matter of tuberculin, however, it seems to me that the source of great and not unnatural dis-

appointment lies in the apparent failure of the establishment of a principle. We hoped that a fulcrum was perhaps secured which would enable us to profoundly influence the whole class of infectious diseases. We cannot help feeling that the results thus far reported here and elsewhere indicate that no speedy realization of such hopes is to be expected, to say the least. The sequences of the use of tuberculin are so inconstant, alike from a diagnostic and a therapeutic point of view, that very great scepticism is a necessary outcome.

DR. A. L. MASON: I agree with Dr. Shattuck in his last remarks, and think that if this mode of treatment fails to fulfil the anticipations, there is no reason why the reaction against it should not be as great as the enthusiasm was premature. The diagnostic value of tuberculin seems to be impaired by the fact that a certain number of cases, undoubtedly tuberculous, do not give the reaction, and other cases which are non-tuberculous do. At least, those are the statements we have from Germany recently, and especially from the Surgical Congress lately held in Berlin, at which certain diseases, notably actino-mycosis and some forms of malignant disease, were said to present the characteristic reactions after injections.

For therapeutic purposes my experience is not large. Two or three cases which Dr. Ernst has referred to came under my care and have been already spoken of by Dr. Bolles and Dr. Rotch, at least one of them has, the case of pseudo-leukæmia. I should like to ask Dr. Ernst if he will state whether the finding of one bacillus in a single examination would be proof positive that that case was tubercular. He came from our out-patient department to the ward as a typical case of Hodgkin's disease, with symmetrical enlargement of the glands, cervical, axillary and inguinal, and development was very rapid. After death almost all the glands of the body were found to be involved, and, as I understand, no tubercular elements were present.

There is one other case which Dr. Ernst mentioned, — the tumor in Douglas's pouch. This patient improved after the series of injections, but the value of that as proof is lessened somewhat by the fact that she had come in in a febrile state with abdominal pain, apparently due to tubercular peritonitis. She was in a fair way to recover I think before the injections were begun, that is the fever subsided, pain diminished, and the abdominal effusion was absorbed. Later, pains started up again and the disease began to be more active, but there had previously been a cessation, so that the patient had been exhibited before the class as one in whom an attack of apparent tubercular peritonitis tended to spontaneous recovery.

With regard to the absence of reaction in tubercular cases the statement also comes from Germany that pregnant phthisical women give no reaction in a certain number of cases.

Although a good many cases presented themselves in my wards at the City Hospital for treatment I found only four which seemed to me suitable, in whom the disease was incipient at one apex with bacilli in the sputa, and in these four after a short time the injections were interrupted because the patients were made more uncomfortable. Three of them passed out of sight. One, perhaps the least advanced of all, with early phthisis at the right apex, is now at the Channing Home, having failed rapidly since the treatment was instituted. The indications for stopping it were great

distress in breathing, pain in the diseased portion of the lung, and general discomfort, although in this case there was no febrile reaction whatever from the injection of one or two milligrammes of the Koch material.

One case of lupus only came under my care, sent in from the out-patient department by Dr. Tilden. This case was under treatment for four months, and has lately been taken away from the hospital by the parents, as there was no improvement whatever. The amount of fluid injected finally was one centigramme every other day.

DR. J. C. WHITE: After listening to the carefully prepared report of the reader one turns back for a moment with wonder and surprise at the character of the statements which first came to us from the home of the discovery of this reagent, and one wonders if it can be really true that these statements, which were made with every appearance of certainty, had really any foundation for their existence at all. It is now impossible to believe that they did, and one is inclined to account for the mental condition which these reporters and investigators were in, either on the basis of the peculiar form of mental condition — I hardly know how to classify it — which the discovery of new remedies seem to produce in some physicians, or else — and this is the most charitable view I think to take of the matter — that the cases which were at first reported, in which those remarkable cures were claimed to have been made, were cutaneous tuberculosis, and were reported by physicians who could have no educated judgment in such cases at all. They were not familiar with the ordinary events that take place in such forms of tuberculosis, periods of activity and retrogression, spontaneous changes. They were not dermatologists, and had no special knowledge about the disease. Certainly the reports made by the most competent dermatologists in Europe, a committee of the French Academy of Medicine, where the matter was studied with the greatest care, show, at least, that such results were not obtained in France, nor were they obtained in Madrid or Vienna, nor in various other parts of the world; and the statements given us to-night by Dr. Ernst certainly confirm these later reports.

Those claims were that this remedy had great diagnostic value, and that it also had curative properties to a marvellous degree. I shall confine any remarks I may make upon this subject to my observation in cases of cutaneous tuberculosis, which is the proper field for such observations, because we have there the means of making the real diagnosis in the beginning, and also because we can see the changes which may ensue.

Now it was early shown, and has been constantly demonstrated since, that it has no diagnostic value whatever, because in some cases it does not impress tuberculous tissue at all, and in other cases it does. It does not impress it in any diagnostic or peculiar way, for it produces precisely the same tissue changes in other forms of dermatoses; for instance, in the lesions of syphilis, carcinoma, lichen planus and leprosy. Moreover, it has absolutely failed to make any local impression whatever in some well-marked forms of tuberculous disease of the skin. It will affect one portion of the skin affected by tuberculosis, and another exhibiting the same character of lesion not in the slightest degree. It will affect one lesion and not another in individual cases. It will affect some cases in a very marked degree, and fail to affect other cases of cutane-

ous tuberculosis, so that it may be fairly said that it has been demonstrated that it has no practical diagnostic value whatever.

The other claim was that it was curative, and the reports that came at first of absolute cures in the early weeks of its use, we are all familiar with. Now the fifty cases of cutaneous tuberculosis which were studied by this committee in Paris in the Saint Louis Hospital in the most careful way terminated in not one cure. In not one of these cases which Dr. Ernst has reported of cutaneous tuberculosis to-night does he claim a cure. Seven or eight of the cases I had had under observation a long time previously, and had treated in various ways, and was familiar with their appearances. Some of these cases were affected by the injection of this substance. They became inflamed, — the tissues in which these lesions were seated. In one of the patients in which this change was most marked the normal cutaneous tissues all over the body became inflamed and to a very marked degree; and the patches of cutaneous tuberculosis in her case, which were already seats of chronic inflammation, were simply additionally inflamed. Now that is the only change that I have seen in all these cases, — simple additionally inflammatory reaction set up around some of the lesions, and not at all around other lesions in the same patient. In some of the individuals affected not the slightest local reaction took place, although general reaction took place, and the local and the constitutional reaction in these cases were in no way proportionate.

One of the cases that has been alluded to was first under Dr. Knight's care for lupus of the throat, then under my care for cutaneous tuberculosis; and she recovered under my parasiticide treatment, which I generally employ, remained well three or four years, then the disease was neglected, got a new start, and she was sent into the hospital. That was a case in which it was supposed a cure was going to take place. It is not cured. It stopped being acted upon by the remedy, and she is now under my treatment again in a very much worse condition than when she entered the hospital. I have within a fortnight run a stick of nitrate of silver down nearly an inch into the boggy cutaneous tissues of her face. Probably at the time she entered it could not have been made to penetrate more than one-fourth to one-third of an inch. In other words, she has become a great deal worse than before she entered the hospital under this treatment. How much the inflammation set up by the treatment about the parts had to do with the more rapid advance of the disease it is impossible to say.

Another case of marked disease was not influenced in the slightest degree; not the remotest degree of hyperæmia was set up around the lesions after two months of the constant use of this remedy.

In no one of the seven or eight cases which I have observed has there been any apparent cure, nor any change to warrant the conclusion that a cure could take place in my opinion. Certainly no real improvement has taken place in any one of them. Of course, seven or eight cases are very insignificant when contrasted with the large series of cases the French dermatologists have reported upon. Under these circumstances what hope is there for benefit by continuing these experiments? I think Dr. Ernst was the first to suggest stopping the treatment in most of the cases himself. He was satisfied that, at any rate for the time, they were not going to improve any more by the contin-

tion of the injections. I cannot see myself that in this remedy, as it now exists, with our knowledge of its action there is anything to warrant the persistence of the experiments in this direction. I think that it has given us an important lesson in many ways, and that under proper scientific study, independently of clinical experimentation, it offers a promising field of what may possibly be attained by such work in the future.

DR. SUMNER: I had five cases under my care, all cases of phthisis pulmonalis. In all there has been an improvement; by improvement I mean gain in weight, either slight gain, or standing still of the physical signs.

DR. G. B. SHATTUCK: I have had five cases under my personal observation, most of them since the beginning of January, that is, cases which I have treated myself. I have had an opportunity to follow other cases that were under the treatment of Dr. Ernst at the City Hospital, and under the treatment of other gentlemen. I have not written up my cases. I may do so later. There happened to be among those five two cases which showed remarkable improvement, and I made a few notes in regard to them, in order to present them this evening, as I had the impression that the general tone of the discussion would be somewhat of the nature which it has shown itself to be, that is, rather unfavorable to the remedy. At the risk of demonstrating that I am a belated example of the unclassified mental disorder to which Dr. White has failed to give any name, I will read these notes. The cases are interesting and instructive, not simply because they improved, but for some other points in regard to them. Before giving the results in these two cases, I should like to state positively what Dr. Ernst has stated in regard to his cases, that I am trying to give the facts, without any prejudices, as nearly as I could get at the facts, and do not wish to be understood as saying that the results, which apparently occurred in these cases, were due to the treatment, but they did follow the treatment.

CASE 1. M. O'N., female, sixteen years old. Landed in America early in October, 1890. Previously well, presently began to cough. Catamenia ceased. Parents living and well. Six brothers, five sisters; one brother with phthisis came to the City Hospital, December 5th. Percussion and respiration good throughout right front; left upper front, down to about third space, somewhat dull. Respiration broncho-vesicular, with medium, fine and subcrepitant râles. No change in voice or fremitus. Percussion over left back fair; coarse, medium and fine moist râles. Temperature 101°, pulse 100, respiration 40.

January 2, 1891. Left front, to third space, dull on percussion; respiration broncho-vesicular; medium and fine moist râles. Upper left back, occasional fine, moist râles. Lower third of right back, dullness, broncho-vesicular respiration, fine and medium moist râles. Weight 115½ pounds. Patient has been losing flesh and strength. Bacilli in the sputum.

January 3d. First injection .0005 gm.

Injections twice a week in gradually increased doses. January 21st, weight 126 pounds; 30th, 132½ pounds.

February 6th. Signs have improved over the left upper front and lower right back.

February 18th. Slight dullness and a few fine, moist râles on forced inspiration, left upper front; some over lower right back. Sputum much diminished.

March 30th. Weight remains the same. Good ap-

petite. Sleeps well. Good color. Catamenia returned in January, and has been regular since. Almost never coughs. No expectoration. Last examination of sputum, no bacilli. Does much work about the wards.

April 12th. Lower third of right back perceptibly dull. Respiratory murmur perceptibly altered. Quite numerous fine, dry, crackling râles heard at end of forced inspiration, over left front. Percussion slightly dull; occasional fine, dry râles with forced inspiration. Went to Ireland. Thirty injections in all; largest amount .016 gm.

CASE II. J. W., female, twenty-seven years old. Family history good. Entered the City Hospital, on account of stenosis of the larynx, early in November, 1890.

Examination of the throat, by Dr. T. A. DeBlois, November 6th: Uvula, tonsils, upper portion of pharynx red, but no ulcerations. Larynx filled with thick, yellow, tenacious mucus. Glottis and arytenoids thickly studded with ulcerated areas of a tuberculous nature. Examination of lungs: Left filled with sibilant and sonorous râles front and back, no change in percussion. On the right side there was dullness in front as low as upper margin of fourth rib, and behind as low as angle of scapula; bronchial breathing over these areas with coarse, moist râles; sibilant and sonorous râles over the rest of the lung. Tracheotomy was performed in the service of Dr. M. F. Gavin, on account of the laryngeal stenosis.

January 11, 1891. Patient steadily losing strength and weight. Weighs 89 pounds. Examination of lungs: Area of dullness under right clavicle and over upper right back; respiratory murmur over this area broncho-vesicular, occasional fine, moist râles. Patient has worn tube since tracheotomy. Bacilli in sputum.

January 12th. First injection .0003 gm. Injections were continued in increasing amounts twice or three times a week up to March, and after that once a week with occasional intermissions. Twenty-seven injections were given in all, the largest amount was .017 gm.

In February, the tube was removed; in March the weight was 113 pounds, a weight which was retained with but little variation. The active signs over the upper right lung disappeared, the sputum diminished, and no bacilli were found in the last examinations. The voice had returned in a great measure in May; there was a good degree of strength and a temperature, which, though at times irregular, varied much less from normal than before. The examination of the larynx by Dr. Farlow, May 7, 1891, showed left false cord nearly normal; left cord white and nearly normal; left arytenoid smaller and less cicatricial looking; right arytenoid smaller; right cord and false cord less red and swollen; though changes not as marked as on left side. Movement of glottis and cords much greater. Arrangements will be made, it is hoped, to keep this patient under observation under favorable surroundings through the summer.

In regard to the general question of throwing aside this treatment or continuing it, I agree with the concluding editorial paragraph to which Dr. Ernst alluded and it expresses my frame of mind, a frame of mind shared by the gentlemen who discussed the subject at the meeting of the New York Academy of Medicine last week, where Dr. Kimicutt and Dr. Jacobi reported a large number of cases. I believe these gentlemen

took a more favorable view of the possibilities of this treatment from their experiments than has been taken here. Those taking part in that discussion, not only took a comparatively favorable view of the possibilities of this treatment, but all certainly seemed to think it worth while to continue the experiments.

Dr. F. C. Shattuck has alluded to the uncertainty and the variability of the results obtained. Now it seems to me that that is what we might expect from the extreme variability of the methods in which the treatment has been applied. We have the doses varying from one-half of a milligramme, I know a number of cases where the doses have not been over two milligrammes and I don't think we can draw any conclusion from those cases — up to the large ones which Dr. Warren has spoken of. One thousand milligrammes has not been an unusual dose abroad. Again where the frequency of repetition has varied from several times a day up to once a week, it is very natural that we should have a good deal of variability in the results, but it does not seem to me that it can be fairly considered a condemnation of the treatment. A good deal of the uncertainty, it seems to me, arises from the fact that Koch's hand was so forced at the beginning. Men are now experimenting in the way that it would have been better to have had experiments made earlier. Nobody is in a position to say, in general, whether it is better to give small doses frequently, repeated or large doses at longer intervals. And whereas we are not yet in a position to say this in general in regard to the treatment, we certainly are still less in a position, as yet, to determine in any individual case whether it is better to handle that individual case in this way or that way; and it seems to me, that rationally and reasonably, we should be willing to take sufficient time to determine such points as these.

Dr. BRADFORD: A word in addition: The patient entered Dr. Gavin's service and was there tracheotomized. She remained there two months, and I can testify to the fact, that although the treatment was carefully carried out, her condition was a pitiable one, and so pitiable that she was on the point of being discharged as incurable. No change took place until Dr. Shattuck commenced the treatment by tuberculin, and her improvement has been steady since then. She had been a long time in the hospital steadily growing worse, and under the same conditions precisely she has steadily improved under the injection of tuberculin.

Dr. J. G. BLAKE: My experience is confined to the observation of two cases, both middle-aged men with well-marked physical signs of tubercular disease in the lung. The observation was carried on for a month. My impression was very favorable as to the good effect of the treatment. I believe there is no question about increase in weight, and according to the report of the patients a diminution in the amount of the expectoration and a lessening in the frequency of the cough. I questioned them very closely almost daily while they remained under my observation, and certainly the impression which I received then was that the condition of these men was better than it would have been under any system of treatment which we have been accustomed to apply in similar cases. I believe the men left the hospital before the treatment could be fully tried, but the month they were in my ward their report was to the effect that they were steadily improving. What became of them afterwards I am unable to say. Those two cases left a very favor-

able impression on my mind as to the value of this remedy. Perhaps if they had continued longer they might have reached a stage of retrogression, but they had not done so. Dr. Ernst has reported the cases to-night.

Dr. JEFFRIES stated that he had recently published some cases in the *Boston Medical and Surgical Journal* without any conclusions, and that he had now no conclusions. We began without conclusions in reference to tuberculin. We were told it was of diagnostic value, and that it was curative. Now we were making experiments to find out whether it was or not. He supposed in a few years we would know, but at present he did not consider that he did.

Dr. F. C. SHATTUCK: When I spoke of the inconstancy of the results I was not speaking of the inconstancy of the results reported from all sorts of different places, treated in all sorts of different ways, but of the results we have seen in Boston where the cases have been treated with practically the same dosage and at practically the same intervals, and I think it is striking. Some react and some do not.

Dr. G. B. SHATTUCK: I do not think it is any more striking than one would expect of most any treatment where it is applied under such a variety of conditions and in such a variety of individuals.

Dr. ERNST: There seems almost nothing for me to say excepting in reply to one or two of the questions that have been asked. I have tried to report these cases as carefully and as cautiously as possible. If I had followed the conclusions in all of the cases, of the gentlemen in whose services they occurred, I think the proportion that were relieved would be increased. One of them is the sinus of the wrist of which Dr. Bradford spoke, and which he considered relieved. The case was relieved; but I have tried to be careful not to call a case relieved where I do not feel that everybody must agree that it must be so, and I have marked it as not relieved.

In regard to the child at the Children's Hospital, I did not know that she was at all in a condition to be about upon crutches. I spoke of that as one point in the conclusion that she was relieved. I certainly received the information from the house-officer that she was in a desperate condition before treatment was begun and had not been out of bed for a long while.

Dr. Bolles asked whether I believe that pneumonia may be caused by this treatment. I practically know nothing about it at all. I quoted Virchow's opinions at length, because I think that anything he says is worthy of all confidence, and if he saw appearances which made him feel justified in giving voice to such a suspicion, I should think it was a possibility to be looked out for.

In regard to the case of pseudo-leukemia I do not know whether Dr. Roth knows that the physical signs in the lung are on the surgical records upon December 2d, so that it is not possible that they came as a result of the treatment, and that is the reason it seems to me that we are perfectly justified in not attributing any of the physical signs to the treatment.

Dr. RORER: I spoke of it as being a case of pure pneumonia in a pseudo-leukemia having nothing to do with the ingestions. I said I supposed I had a case of leukemia, but that at the autopsy it was found to be not a case of tuberculosis.

Dr. ERNST: The autopsy records say acute fibrinous pneumonia, acute pleurisy. The man himself told

me that he got a chill because the nurse left the window open on him. The temperature in the next three hours showed a rise of nearly six degrees. In reporting this case of pseudo-leukemia I took especial pains not to give the specific name of tuberculosis to it. I most emphatically should not consider that the discovery of one bacillus in the sputum would justify me in making a diagnosis of tuberculosis. I believe I made the mistake in reading the record of using the words "bacilli were found in the sputum." It is perfectly true that a tubercle bacillus was found in the sputum upon February 11th. What I said in regard to that fact was that the presence of that bacillus made it necessary to suspend judgment in regard to the case, and not draw the conclusion that it was absolutely fatal to any diagnostic value of the material.

The uterine case that Dr. Mason speaks of is not put down, and not spoken of as a case of tuberculosis. It is distinctly spoken of as not presenting any signs of tuberculosis, showing no macroscopic evidence of tuberculosis, and I did not know that it had been considered a case of acute tuberculosis; and was getting well before the treatment began. I do not think there is a record of that.

Dr. G. B. SHATTUCK: A point which has not been especially dwelt upon this evening is, in justice to Koch it seems to me, a point we always ought to bring up and to dwell on; that from the very first commencement of the use of his remedy he has insisted upon the stipulation that in pulmonary tuberculosis we should apply it to the very early cases, and according to almost all the reports which we have, it has been applied to a very large number of cases of late tuberculosis, and cases of early tuberculosis are the exceptions, and that is because it is excessively difficult in hospital practice, where we have to use this thing, and where it ought to be used, to get those cases.

## NEW HAMPSHIRE MEDICAL SOCIETY.

The New Hampshire Medical Society held its One Hundredth Anniversary at Concord, N. H., commencing June 15th.

Dr. E. E. GRAVES read a paper on

### THE TREATMENT OF EPITHELIOMA BY MAGNESIUM SULPHATE.

He reported eight cures where the treatment was three drachms of sulphate of magnesia to one pint of water, a teaspoonful of the solution taken four times a day. After the parts have been cleaned, a little dry boric acid or a small amount of carbolic acid ointment was used. No other local treatment was given. In most of the cases when the disease was first observed by the patient, it was manifested as a hard scale on the surface of the skin, or situated on a button-like eminence on the face, which had been there for many months and perhaps years. Some slight itching or stinging sensation might cause the patient to remove the scale for several times, and it might become a little thicker and harder each time, when finally on being removed there would be found a moist ulcerating surface which soon became deeper and broader. The edges became indurated and elevated, and we finally have a growth of a nodular character which by commensurate increase on its circumference kept a little in advance of the destruction which was going on in

the centre. There may have been a mistake in the diagnosis of all these cases; but it is a fact that whereas we had growths or enlargements of an elevated character with round or oval bases, whose summits were ulcerated or dark in color, with a discharge of an ichorous character, and those growths increasing perceptibly from one week to another, both in depth and in circumference, and pain of a pricking character, we now have a surface which is natural and healthy in appearance, and nothing to show it was ever diseased in the least.

Dr. J. J. BERRY read a paper on

#### THE INTERNAL USE OF GERMICIDES.

His conclusions are as follows:

(1) The internal use of germicides is valueless in most cases of systemic infection. While they may alleviate symptoms, they possess no curative properties.

(2) Such agents have at times a beneficial effect upon acute gastro-intestinal diseases, and are of some value in those of a more chronic nature.

(3) Their remedial effects are not always due to the germicidal properties.

(4) Systemic as well as local disinfection, when required, is effected far better by eliminatives than by germicides.

Other papers read were: "Four Medical Men of New Hampshire," by Edward French; "Report on Gynecology," by Dr. Ellen A. Wallace; "Looking Backward," by Dr. A. P. Richardson; "Medical Education in New Hampshire," by Prof. C. P. Frost; "New Hampshire Surgeons and Surgery in the Past Century," by Dr. John W. Parsons.

On June 16th, the Society and its guests went for an excursion, taking the train at Concord at 10.30 A. M., to Lake Village, thence by rail, skirting the shores of Lake Winnepiseogee, to Alton Bay, where they took a steamer for the Weirs, and from there returned to Concord by rail.

#### THE ANNIVERSARY DINNER

was served at the Eagle Hotel, in the evening, and about one hundred and fifty guests sat down to the tables. The officers and guests of the society were seated at a table in the centre of the dining-hall, and among them were the President, Dr. Lyman B. How, Governor Tuttle, Mayor Clapp, Senator Chandler, Attorney-General Barnard, Bishop Niles, Dr. H. O. Marcy, Dr. D. W. Cheever, Dr. A. H. Johnson, Dr. Charles W. Lindsey, Dr. William H. Palmer and Dr. H. W. Williams.

At the close of the banquet the Anniversary Chairman, Dr. WILLIAM T. SMITH, of Hanover, said:

It is my privilege and pleasure to welcome, in the name of the society, our honored guests and fellows. They have to-day seen something of our beautiful scenery; they have listened to something of the work of the society; they have heard something of its history and we ask them to rejoice with us on this occasion. Why should we rejoice on this centennial of our society? Why does it awaken our enthusiasm and inspire us with devotion? Because the society is the embodiment of our ideal. The great men who founded it put into it whatever was best for themselves, and their successors have contributed of their best during the century which has passed. And when we come up here and make our contributions from year to year, we become a part of the Society and it becomes a part of

us; its possessions, the accumulations of a century, are ours; and we are elevated and inspired, and we go back to our work stronger and better men. The true history of this Society is not alone the history of its great men; it is also the history of the humble and obscure practitioners scattered among the hills and valleys of the Granite State, who are putting to the test the theories of our art, and whose experiences are the storehouse from which material for scientific generalization is drawn. We are all descendants of Josiah Bartlett, more or less remote; but the name of one gentleman here proves his ancestry. I call upon our learned President, Dr. Lyman Bartlett How.

Dr. How: *Mr. Chairman, Fellows of the Society, Ladies and Gentlemen:*—I have no doubt you have been wondering why it was that a man born in Massachusetts should be elected president of the New Hampshire Medical Society, and why I should be called upon to make a speech on this occasion, since it is well known that I am not an orator. On my mother's side I am related to the Dearborns and the Choates. My maternal grandfather was a relative of John Henry Dearborn, who was a physician and was Washington's right hand man in the Revolutionary War. My maternal grandmother was related to the Choate family of which Rufus Choate was a member: so you see there is a hereditary tendency both to blood and eloquence; but, as my homeopathic friends would say, it is in a highly attenuated form, and I cannot satisfy myself that the attenuation in this case increases the potency. On my father's side I am related to the Hows, some of whom may have been very distinguished. Dr. James How, of Rochester, was a very early member of this Society, he was a surgeon during the Revolutionary War.

Looking around the table, I see delegates from our sister societies. In behalf of our own society I voice the unanimous sentiment when I return to your societies hearty thanks for your sacrifice in coming up here into New Hampshire this extremely hot weather. It has not been the fortune of New Hampshire men to make many discoveries in the science of medicine. We have been practical men here. We have held a very honorable position, perhaps, in some of the departments of operative surgery. No matter on which side of the State lines improvements and discoveries have been made, we feel that these discoveries and improvements are the common heritage of us all; and in the future as in the past may these sister societies march shoulder to shoulder firmly in the spirit of our profession. To day we have had the privilege of inhaling New Hampshire air upon the lake. To these mountains, no doubt, and to the clear and sparkling water that bubbles out of these everlasting hills, the vigor of our ancestors was in part due. I propose that we arise and in this beverage drink to the immortal memories of those worthy founders of our Society.

Brief addresses were made by GOVERNOR TUTTLE and MAYOR CLAPP, extending to the Society and its guests a cordial welcome to the State and city.

Dr. REV. W. W. NILES paid an eloquent tribute to the devotion and self-sacrifice of the medical profession.

HON. WILLIAM E. CHANDLER was next called upon. He paid the tribute of his homage, respect and admiration to these beloved physicians who give their powers to the wearisome and perilous labor of healing the sick, which absorbs their nights and days alike and exposes them to contagion and pestilence, while

it exhibits to them humanity only in disease and death. In one respect there is a greater responsibility upon the medical profession than upon either of the other so-called learned professions, and that is in thoroughness of preparation which physicians should have. A badly educated minister cannot do much harm provided his heart is right. An ignorant lawyer does not do much mischief because, if he loses his client's case, it is only the loss of money, and his client will soon find him out. But a man who enters upon the practice of medicine without long years of careful preparation is guilty of a crime against humanity. He believed that the profession in this country, as well as in others, are conscientiously endeavoring to elevate the standard, and young physicians taking the field to-day are better prepared for their work than the young men of other professions.

ATTORNEY-GENERAL BARNARD congratulated the society for containing so large a number of good-looking men. He was not aware that this little State, which he thought so healthy, could support such a large corps of physicians; and he was also surprised that so many could be spared from their patients for three days at a time, but supposed that each physician left more medicine at his last visit than usual, the same as the ice-man leaves on Saturday enough ice to last over Sunday. He observed great improvement in the sanitary condition of the people during the last twenty years. In villages where typhoid fever then raged it is now hardly seen. People are living better, enjoying better health, and life has been extended by at least ten per cent.; and this is owing very largely to the efforts of the medical profession, who have made earnest efforts to educate the people in sanitary matters.

DR. MARY A. SMITH responded to the toast, "Women in Medicine." She said it was a matter for congratulation and encouragement that the Fellows of this Society should have deemed this toast worthy a place in its centennial exercises. Women physicians are here to stay. All they ask is an open field and fair play. In order to obtain a satisfactory medical education, she was compelled to become an exile in a foreign land to seek the opportunities which were denied her here. But the light begins to break, and it is to be hoped that it can soon be said that throughout the length and breadth of this land no medical school had refuse to women the opportunities it gives to the other sex.

DR. H. O. MARCY was invited to speak for the American Medical Association. He said that Association is not quite half as old as the society whose centennial we celebrate. Some have thought that she took the position of step-mother to these eastern elder maiden sisters, and some of these eastern elder maiden sisters have doubted if she ought to come into the relationship he holds. But the Association has certainly been a fruitful mother, and she gathers into her family from every State in the Union, and represents nearly a hundred thousand physicians, who are brought into accord through this central organization. The progress of our profession during the last twenty years has been marvellous; surgery, an art at the one end, has become a science, and in the field of medicine we had one disease after another yielding to scientific investigation. Twenty-six States of the Union have adopted laws for the regulation of the practice of medicine, and we may predict that before

long no physician will be permitted to practise until he has shown to a competent board that he is prepared in a certain large measure to fulfil his trust. Sanitary science has made great progress and is in itself a profession. The problem of the future is to be able to mass people together in great communities, while each individual may breathe as pure air as the dweller among New Hampshire hills, each may drink water as pure as that of the beautiful lake we sailed upon to-day, and build upon a soil as free from the dangers of miasma as are the granite hills of this State. It is but a short time to which we are looking forward for the happening of one of two things; either the science of to-morrow will give us the means of purifying our present water-supply in the city of Boston, or New Hampshire will be asked to furnish us with the pure waters of Lake Winnipiseogee, which I have no doubt she will be glad to do.

DR. A. H. JOHNSON said that hitherto a visit to New Hampshire had been associated with a feeling of refreshing by reason of relaxation from toil and the enjoyment of cascades and rushing streams. But to-day he came weighted with responsibility, bringing the salutations, congratulations and expressions of high esteem, best wishes and God-speed of more than seven hundred members of the Massachusetts Medical Society. Manifestly it would be impossible to transmit so great a volume of kind thought and feeling by any form of words which the time allowed; therefore many members of the Massachusetts Medical Society have responded to the invitation to attend these exercises, not to adequately voice the sentiment of the body they represent, but to manifest by their presence their desire to maintain the friendly communication between the societies which has existed for so many years. The natural scenery which we have admired to-day is a symbol. What more unlike than mountain and river? Yet without the former we cannot have the latter. Men as counterparts bring into existence better forms of thought and action than as homogeneous workers. The river makes its way to the ocean, thence to be lifted by the sun, and symbolizes by its flowings and distributions from the hills the courses of human thought and action. The spirit of learning for philanthropy's sake lifts us to heights of medical knowledge whence our acquired powers, through these societies, flow out to the vast round of varying human needs and promote the increase of life and happiness. The New Hampshire Medical Society,—May the wisdom and honor which it has obtained in the century past prove the root out of which shall develop a growth which shall bear abundant fruit for all seekers of medical learning, and which shall sustain all promoters of professional fraternity and enthusiasm in our country.

DR. D. W. CHELVER said that as a son of New Hampshire he could not but feel pleased to be a visitor to this Society under such pleasant circumstances, and as a son of his father he could not but have been gratified with the honorable tribute which had been paid to his worth and excellence by one of the speakers during the meeting, as one of the earliest and most successful medical pioneers of medicine in this State. It is doubtful if the sons are equal to their fathers. It was their energy and talent, especially in surgery, which founded in this State, at Dartmouth College, one of the first medical institutions in New England. A great obligation is imposed upon us to keep up to

their high standard the work which they began. Harvard Medical School has gone through two severe convulsions in the reforms which it has endeavored to carry out. About twenty years ago it adopted a graded course, and made it longer than the former. As soon as this change was in successful operation, a second radical change was to require a preliminary examination in certain elements of liberal education. Next year, a third step is intended, and a four years' course will be required. Harvard Medical School feels some pardonable pride that, in the face of many obstacles, it has done something to advance the standard of medical education and place it more nearly on a level with that of other countries of the civilized world. Medicine is not what it used to be, and is not studied as it used to be. Modern discoveries and inventions have converted what was before an empirical art into a true science; and apparently we are on the eve of still larger discoveries, especially in bacteriology and microscopy, which will ennoble our art still more, until it shall have a place among the sister sciences as their equal.

PROF. CHARLES W. LINDSEY said that he suspected that some practical joker had informed the chairman that he was a member of the Connecticut legislature, which had never done anything but talk. If he were at home he would not be called upon to speak, because there, as well as here, there are many better speakers. He compared the practice of medicine when he was young with the practice to-day, illustrating the differences with amusing instances. We can imagine that the practitioner of forty years ago would be surprised could he be called in consultation with us in these days. What would he think of bacteria, germicides, and all these things? Almost everything in the way of *matéria medica* has been changed since that time. There is another change which is not so pleasant to contemplate. Not only are there the morphine habit, the alcohol habit and the opium habit, but there is the dose habit. The newspapers will not mention this, because they derive a good deal of their income from encouraging it by way of advertisements of medicines accompanied by ingeniously written descriptions of symptoms. A clergyman told an anecdote about one of his parishioners who had fallen into this habit, to the great distress of his family. His wife applied to the clergyman, and asked him to use his influence to dissuade her husband from the foolish habit. "Have you prayed for him?"—"Prayed for him! I go to church for nothing else, sometimes, but just to repeat that petition in the prayer-book which so directly applies to his case."—"I do not know what passage you refer to."—"Why, you know where it says, from all false doctrine, good Lord, deliver me." That petition ought to be put into the liturgies of all denominations, and at the head of all the big advertisements in the newspapers.

DR. WILLIAM H. PALMER said that the New Hampshire Medical Society commands honor by reason of its age and also for what it has accomplished. In the annals of this country are found the writings of its representative men. They are met with every day by the student of medical literature. Very important decisions have been rendered by an eminent jurist of this State establishing the important truth that a person may know that the act he is doing is wrong and in violation of law, yet be irresponsible for want of will power. It has taken lawyers a long time

to accept this teaching of medical science, but to-day the doctrine of your eminent jurist is finding followers in every State in the Union. It is remarkable that two States here to-day should claim the honor of introducing women into fellowship. I enter a claim for Rhode Island. If our secretary does not find that Mrs. Dr. Tyng was the first lady admitted into fellowship by any association in this country, his resignation will be in order. For a long time Boston and Newport were the only important towns in New England; yet not until 1812 was the Rhode Island Medical Society founded. The cause of this inertness was doubtless the "soul liberty" doctrine of Roger Williams. It grew into the idea of individual liberty. There is a feeling in Rhode Island that every person has an extraordinary amount of individual right. That is what kept it so long out of the Union. No forward step can be taken in medical legislation for it would be in violation of the doctrine of "soul liberty," and a man has the right to employ whom he will to kill him, and you cannot interfere.

DR. WILLIAM CHILD was called upon to respond to the sentiment, "Let a man step to the music that he hears." He said this is a sentiment you would naturally expect a young lady sophomore would select; but after all there is a good deal in it. When he started out he was not quite sure whether he had better be a doctor or a minister, but he finally concluded to be a doctor, and he had been digging away at it the best he could ever since. Moses heard the music in the oppression of his brethren, and in the burning bush, and again in the thunders on Mt. Sinai, and he stepped according to the music that he heard. But not having enough faith he did not get quite up to the mark set for him, and he did not get into the promised land; and the angels buried him. David stepped according to the music that he heard, though Satan got some notes into the score that set him stepping pretty high. But he has been the sweet singer of the Jews and Christians for all ages, and no doubt his psalms have been acceptable to the Almighty. Alexander, Caesar and Napoleon stepped pretty high to the music that they heard,—but the angels did not bury them. There are physicians who, like Moses, hear the music, and are earnest and faithful in their work; like Moses they do the best they can, and they do deserve to be buried by the angels. There are those who march as David marched; they intend to march well, but the devil gets a few notes into the score, and they do not make such men as they would if they had marched to the true music. Then we have smart, keen men who march as Alexander, Caesar and Napoleon marched. In former years men went into the medical profession with their elbows out towards everybody, and their main object seemed to be to raise themselves on the downfall of some one else. It is not so much so to-day. We have heard the praises of the dead ones rung to-night, and that is right; but I think some mention ought to be made of the living members of the Society, to whom so much is due for its prosperity and for the successful efforts of the board of health. I refer particularly to Dr. Conn and Dr. Watson. When they die, we will get up here and praise their memories; but what will they care about that? What will they know about it, perhaps? They should have the credit for what they are doing while they are living; and every member of the Society will heartily cheer these sentiments.

DR. H. W. WILLIAMS made brief remarks, urging the members of the Society and the eminent guests of the legal profession to do what they could to obtain the passage of healthful legislation to regulate the practice of medicine.

In conclusion, the CHAIRMEN said: *Ladies and Gentlemen*,—Our centennial day is ended. May God bless the New Hampshire Medical Society, may God bless us all, and when another hundred years have rolled away may those who stand where we stand have the same reason to be proud and glad that we have to-night.

On June 17th the reports of the council, delegates, and officers were presented and acted upon; and the election of officers was held, which resulted in the following choice: President, Dr. Moses W. Russell, Concord, N. H.; Vice-President, Dr. James H. Wheeler, Dover; Treasurer, Dr. Daniel S. Adams, Manchester; Secretary, Dr. Granville P. Conn, Concord. Executive Committee, Dr. C. R. Walker, Concord, Dr. G. D. Towne, Manchester, Dr. J. R. Kimball, Suncook; Anniversary Chairman, Dr. George D. Towne, Manchester.

### Recent Literature.

*Hereditary, Health, and Personal Beauty.* By JOHN V. SNOOKMAKER, A.M., M.D. Philadelphia and London: F. A. Davis, Publisher.

This book of 422 pages is intended as a contribution to popular instruction in matters of health, and all things directly appertaining thereto.

A wide range is taken by the writer, and many matters are discussed *en passant* that seem to have little to do with the subject. The writer often shows a great fertility of expression and picturesqueness of diction; but, after reading many of the chapters, the impression of an astounding verbosity is all that we can retain.

In the introduction, the views of August Weissmann on heredity are discussed and combated with a denance of Darwin and his followers, and Chapter I then proceeds to treat of the general laws of health. Then follow chapters on the law of life and growth, man's spiritual and physical place in nature, the evolution of the present era, the source of the beauty of the fair sex, the art of walking, and the evolution of the American girl. A good illustration of the author's exuberant style is offered in the chapter on the phenomena of evolution in the present era, where the following Macaulayism is to be found:

"In this democratic America, where only a few years ago the tail of the British lion used to be twisted on the Fourth of July and other high days and holidays, and the public prints never tired of descanting on effete European monarchies and the absurdities of titular rank, valuable invoices of American girls yearly go to supply foreign needs, so that the day may come when the New Zealander, sitting on the broken arch of London bridge to view the ruins of St. Paul's, may find among the neighboring drift a stratum rich in specimens of an extinct female American type, associated with collapsed money-bags, while the opposite shores of the Atlantic may show contemporaneous depots of humpes and microcephalous dudes. These, mingled with crania evidencing a highly intellectual

status of present dwellers on the soil, will be the puzzle and despair of the future geologist to account for their presence in the midst of an evidently advanced civilization."

In the latter part of the book the practical subjects of bathing, care of the skin, hair and nails are quite fully treated, while short excursions are made into the domain of the eye, ear and teeth. We must acknowledge that these chapters contain much good (and some bad) advice, and also that the writer is frequently most amusing in his style and vastly entertaining, from his numerous anecdotes and citations from history. At the end of the book we find a long array of cosmetic articles and "household remedies" suited to a great variety of the less serious cutaneous affections. The propriety of inserting so many prescriptions in a book intended for popular reading is very questionable, as its effect is likely to be in the direction of encouraging people to make trial of remedies blindly selected from books, in affections which are already largely over-treated before they are brought to the notice of the physician.

*The Intra Cranial Circulation and its Relation to the Physiology of the Brain.* By JAMES CAPPIE, M.D. 8vo, pp. 188. With four plates. Edinburgh: James Thine. 1890.

The present writer's views upon the intra-cranial circulation have already been published, and have met with due consideration from subsequent writers. In the volume before us he presents them again, and lays stress upon their relations to sleep and certain other physiological processes. He holds that "some forces acting at the capillaries have largely to do with the movement of blood through these vessels,"—forces which may be regarded as vital attractions and repulsions. The thesis which he maintains in regard to the circulation is, that the mass of blood in the cranial cavity can be neither diminished nor increased directly. In sleep the capillary forces become relaxed, the veins dilate, and the arteries become less full. The capillaries are drained and the brain substance compressed. A similar condition is supposed to exist in coma. That this hypothesis has a bearing upon the problem of the intra-cranial circulation cannot be denied, and it probably possesses some truth. The author, however, seems to ignore the work that has been done of recent years, notably the exhaustive experimental work of Mosso, which proves pretty conclusively that this hypothesis is only a partial one, and that it cannot be accepted as conclusive.

*Electricity: Its Application in Medicine and Surgery.*

By WELLINGTON ADAMS, M.D. Two volumes, 16mo; pp. 113, 129; 21 and 79 illustrations. Detroit: George S. Davis. 1891.

These two little volumes are a part of the Physician's Leisure Library for 1889 and 1890. They are written confessedly in a dogmatic manner, by a student of electro-physics as well as of electro-therapeutics, and in fact, the electro-physical side distinctly predominates. Electro-physiology and electro-therapeutics occupy only a subordinate place in the two volumes, which are devoted mainly to a consideration of the physics of electricity and to the practical application of electricity to the demands of medicine. Within these limits the work is a success. The first chapter discusses the elementary principles of electricity and magnetism in an admirable fashion. The old notions

which encumber many of the works on electro-therapeutics are exploded, and the elements of electricity are presented clearly and simply, so as to be readily comprehended even by those who have no previous knowledge of electricity. The rest of the first volume and two-thirds of the second are devoted to a practical discussion of the appliances necessary for the employment of electricity in medicine. Such a guide is of extreme value. The many new applications of electricity to medicine, such as the electric light, the electro-cautery, the electric motor, etc., have been disregarded in most of the text-books, the best of which have been written from only one stand-point, that of the neurologist; while the few works that touch upon these matters are written mainly in the interests of some maker of electrical apparatus. The present work favors no one maker. The different pieces of apparatus necessary are discussed from a scientific stand-point; the different instruments in the market are described, and their merits and demerits candidly stated. The author speaks dogmatically, and has pronounced opinions on the questions at issue; but in the main he is a wise guide, and that through a region to which no guide-book has before been issued. The attention of most writers on electro-therapeutics should be directed to his demolition of the prevalent notions that there is a difference between the current from the primary and the secondary coils, and from coils of coarse or fine wire. Static machines, storage batteries, dynamos, electric lights, electric motors, all are described, and much information is given to guide the physician in the choice of apparatus and in its use after it is chosen. The final chapter of the second volume is devoted to a very brief but clear and simple discussion of the principles of electro-physiology and electro-therapeutics. In view of the merit of the preceding portion of the work we could wish that this were fuller, but the author promises a work devoted solely to electro-therapeutics, which we shall await with interest, for, if it fulfils the promise of these two little volumes, it will give us what is much to be desired,—a good modern treatise on the subject; for those we have that are of value are already old and consider the subject chiefly from the neurological stand-point.

*The Genuine Works of Hippocrates.* Translated from the Greek, with a Preliminary Discourse and Annotations. By FRANCIS ADAMS, LL.D., Surgeon. Two volumes in one. New York: Wm. Wood & Co.

This translation of all those treatises of Hippocrates now regarded as genuine, was prepared by Dr. Adams for the Council of the Sydenham Society. The translator's work is admirably done, and the publishers present the two volumes of the Society in one very handsome royal octavo, on laid antique paper, with wide-margined pages, uncut edges and cloth binding.

WHEN IT IS GOOD TO BE AT HOME. — "Well, Maggie," asked a teacher of a little girl, "how is it you are so late this morning to school?"

"Please sir," was the reply, "there wis a wee hairn cam' to oor hoose this mornin'."

"Ah!" said the teacher, with a smile; "and wasn't your father very pleased with the new baby?"

"No sir; my father's awa' in Edinburgh, and dinna ken about it yet; but it was a guid thing my mither wis at hame; for gin she had been awa', I wadna hae kent what to dae wi' it." — *Sanitarian.*

## THE BOSTON Medical and Surgical Journal.

THURSDAY, AUGUST 6, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

### THE SIMIAN TONGUE.

PROF. R. L. GARNER furnished a paper to the *New Review* (June, 1891), upon the Simiau Tongue, in which he gives some details of his efforts to discover whether "articulate" speech prevails among the lower primates, and whether such speech, if existing, contains the rudiments from which the languages of mankind could easily develop. The result of his efforts encourages him to think it is quite possible to find proofs to show that such is the origin of human speech.

Having long believed that each sound uttered by an animal had a meaning which any other animal of the same kind would interpret at once, and observing that animals soon learn to interpret certain words of man and to obey them, replying in their own peculiar speech, Garner thought, if he could correctly imitate these sounds, he might learn to interpret them more fully and prove whether different species of animals had a uniform speech.

He made little progress in his studies in various zoological gardens at different places, until it occurred to him to avail himself of the aid of the phonograph. By recording on phonographic cylinders the sounds made by monkeys, he was better able to learn to imitate them himself, and at the same time by repeating with the phonograph the record made by one monkey to another it was possible to study the behavior of the latter more closely.

In this way sounds indicating "thirst," "hunger," "sick," "weather" "alarm," etc., were picked out. The capucine monkey was found to be the most favorable for study, apparently having the best defined language of any of his genus. The chimpanzee is said to have a strong, but, monotonous voice, confined to a small range of sounds, and affords a fine study while in the act of talking, but there are only three in America at present.

Garner concludes, as the result of his observations, that the Simiau tongue has about eight or nine sounds, which may be changed by modulation into three or four times that number; they seem to be half way be-

tween a whistle and a pure vocal sound and have a range of four octaves and probably all chord with F sharp on the piano. The sound used most is very much like "u"—"oo," in "shoot." The next one something like "e" in "be." No "a," "i" or "o" was distinguished. Faint traces of consonant sounds can be found in words of low pitch, but they are few and quite feeble.

The present state of speech has been reached by development from a lower form. Each race has its own peculiar language, slightly shaded into dialects, and the radical sounds do not have the same meanings in all. The words are monosyllabic. The phonic character of the speech of monkeys is very much the same as that of children in their early efforts to talk, except as regards pitch. It seems to obey the same laws of change and growth as human speech.

When caged together one monkey will learn to understand the language of another kind, but does not try to speak it. His replies are in his own vernacular. They use their lips in talking in much the same way as men do. Their speech is in about the same relative condition to their physical, mental and social state as that of man, and the more fixed and pronounced the social and gregarious instincts in any species the higher the type of speech. They reason from cause to effect, and their reasoning differs from that of man in degree but not in kind. The state of the language of monkeys seems to correspond with their power to think and to express their thoughts.

These reflections, if well founded, lead, of course, to the conclusion that the languages of mankind may be the progeny of the Simian tongue with as much probability as that the races of mankind may be the progeny of the Simian stock.

#### THE BOSTON DIRECTORY AND ITS LIST OF PHYSICIANS.

THE Boston Directory, for the year 1891, has recently been issued. It contains 198,940 names, including the names of about 2,353 persons who have died or removed from the city within the past year. The Directory then contains the names of 196,587 living persons. In the back part of the book the inhabitants are again enumerated under their several occupations. Under the heading *Physicians*, there are enumerated 1,193 names, or one physician to every 165 names.

The list of physicians, so-called, includes 505 members of the Massachusetts Medical Society; 90 members of the Massachusetts Homoeopathic Society, and 13 members of the Massachusetts Eclectic Society. There are also representatives of the Society of Specialists, the United States Medical Society and of the Women's Hospital Society, many of the latter society being also members of the Massachusetts Medical Society. Most of the remaining names are unaccompanied by any sign or name, but several are followed by some sort of designation that is intended to characterize their belief, then act or their practice.

Among these designations are found eclectic, C. S. (which indicates Christian Science), mind cure, health lift, massage, scientist, eclectic and magnetic, vapor baths, electric, lung, massage and magnetism, omni-pathic, midwife, salve, and electric.

This list for the year 1891 differs very little from the lists of the last few years; but when one remembers that there is no legal definition of a physician in Massachusetts, and, of course, no legally qualified physicians, such a list gains an importance which does not rightfully belong to it. Any person whose name appears upon this list is entitled to all the rights and privileges that belong to a physician, and consequently may sign a death certificate; certainly not because of the appearance of the name on the list nor yet to the exclusion of other names not on the list, but in common with others who claim the title of "Doctor." Such certificates go to make up our mortuary statistics. It is a question how much value can be inherent in statistics so made up, but they probably are much better than none at all.

The relationship of numbers to population is interesting. As was mentioned above, one name in every 165 in the Directory is that of a physician. Of course, the names in the Directory do not represent the total population. The population of Boston for 1890, according to the census returns, is 448,439. Accepting that number the Directory shows one physician in 375, certainly a liberal supply of doctors to inhabitants.

#### MEDICAL NOTES.

**PHILADELPHIA POLYCLINIC.**—The Board of Trustees of the Philadelphia Polyclinic and College for Graduates have created a third Chair of Diseases of the Eye, and have elected Professor George de Schweinitz, M.D., to fill the position.

**LEIDY CHAIR OF ANATOMY AND MUSEUM.**—It has been decided to raise a fund for the endowment of a Chair of Anatomy at the University of Pennsylvania, to be known as the Leidy professorship, in memory of Joseph Leidy, who held the professorship of anatomy for thirty-nine years. It has also been decided to raise a fund of \$50,000 to establish a museum to be known as the Leidy Memorial Museum.

**COMPARATIVE MORTALITY IN ENGLAND AND ITALY.**—The gross population of England and Italy is about the same, namely, thirty millions, and while the mortality during 1889 in the former was 511,000, in the latter during the same period it was 820,000. This gives a rate 17.8 deaths per thousand for England, and 27.6 per thousand for Italy. Bad water and the absence of sanitary arrangements in the large towns are assigned as the causes of this high rate of mortality.

**CHOLERA.**—Telegrams from Alexandria, under date of July 21st, state that cholera is increasing at Mecca and Moula in consequence of the massing of

pilgrims; 140 deaths occurred on July 18th and 380 on July 19th, chiefly amongst Turks. Rigorous measures are being adopted to prevent contagion reaching Egypt. No Egyptian pilgrims have been attacked, which is considered to be due to the wise measures taken in connection with the annual pilgrimage to provide as far as possible for the health and food supply, especially amongst the poorest.

**THE MEDICAL PROFESSION IN RUSSIA.**—The total number of qualified practitioners in Russia, says a foreign exchange, last year was 12,521, and of these 409 were women. Thus there are about 8.4 doctors to each 100,000 inhabitants. The distribution, however, of medical men is unequal, as may be seen by the fact that in Siberia there are only 3.8 practitioners to every 100,000 inhabitants. Twenty-one per cent. of the total number of the profession is engaged in the military and naval services. The average age at which a student becomes qualified is 25.9 years, the women students taking twelve months longer than this. In Odessa, the average income is said to be about \$3000 a year, in St. Petersburg \$1850; in Warsaw \$1250; in Moscow \$1400; and with regard to the public services only two per cent. of the medical men are paid more than at the rate of \$2500 per annum, while the salaries for the most part vary between \$750 and \$1250.

**DR. MAX RUBNER**, director of the Hygienic Institute at Marburg, has been appointed to succeed Dr. Robert Koch as professor of hygiene in Berlin. He was born at Munich in 1854, established himself as a private lecturer in the University of Munich in 1883, was appointed extraordinary professor at Marburg in 1885, and ordinary professor in 1887. Koch has resigned his official positions in order to take the direction of the Institute of Infectious Diseases which has been organized by the German Government. It is stated that the Academic Senate will bestow an honorary office upon him, and that this will permit him to lecture whenever and wherever he pleases.

**INTERNATIONAL CONGRESS OF THE RED CROSS.**—The Red Cross Associations organized in the European States which have signed the Geneva Convention have had the custom of holding international meetings, at which the interests of the sick and wounded in war are practically considered, and the arrangements for a more effective and harmonious furtherance of those interests discussed and agreed upon. The first of these congresses was held in Paris in 1867, the second at Berlin in 1869, the third at Geneva in 1881, and the fourth at Karlsruhe in 1887. At this latter it was resolved that in future the congresses should meet every five years, the place of meeting of the succeeding congress being then undecided. The International Committee of Geneva has just proposed that the congress should hold its fifth meeting in Italy next year, and the Central Italian Committee, duly notified of the fact, has completed negotiations with the Government, according to which the congress will meet in Rome, in April or May, 1892.

## NEW YORK.

**COLLEGE OF PHYSICIANS AND SURGEONS.**—The announcement of the College of Physicians and Surgeons for the session of 1891-92, states that on July 1, 1891, the institution became, under the authority of the Legislature, a part of Columbia College, and will in future be administered as such. This merger, which makes the medical department in a complete sense an integral part of the university system, promises largely to increase the usefulness of the medical school, to favor the thoroughness of scientific medical education, and to promote scientific research. The accessions to the teaching force, notably in the department of anatomy and in the physiological, pathological and chemical laboratories permit the realization, to a degree hitherto impossible, of the great opportunities for instruction and research afforded by the excellence of the dissecting rooms, the laboratories, and apparatus. By the new arrangement the members of the Faculty are placed upon regular salaries, which are entirely independent of the number of students.

**OUTBREAK OF SCARLET FEVER IN A HOSPITAL.**—Two children in Bellevue Hospital, aged respectively two and one-half and five years, have been attacked by scarlet fever and transferred to the Reception Hospital at the foot of East 16th Street. One of them, affected with rachitis, had been in the hospital for two years, and the other, under treatment for Pott's disease, had been an inmate for two weeks. The source of the infection is unknown, but it was probably introduced by some visitor to the children's wards.

---

### Miscellany.

---

#### EUROPEAN COLONIZATION OF CENTRAL AFRICA.

**SIR WILLIAM MOORE**, at a meeting of the Epidemiological Society of London discussed the possibilities of Europeans as colonists in Central Africa, a question which has become prominent during the last few years in connection with the attempts of different European governments to develop that continent.

Africa lies almost entirely in the torrid zone, and is the hottest continent of all. So far as is known, for fifteen degrees north and south of the equator there is a mean temperature of from 80° to 85°; in some localities, according to Stanley, 87°. This is only equalled in Central Mexico, New Guinea, and the very north of Australia. Continued high temperature is the most important of adverse climatological factors and next to this is humidity; the two combined as in equatorial tropical Africa being the acme of a climate inimical to the European constitution. The west coast of Africa is perhaps the most unhealthy climate in the world. The east coasts from Cape Guardafui to Natal, present mangrove swamps and low-lying marsh lands, more or less for the whole distance. As regards the interior of Africa there is the Sahara Desert to the north, and the Kalahari sand tracts to the south of the equator, with an immense intervening more or less elevated region, much swamp land, and much forest land, supported by tropical rains, which,

in most localities endure during eight months of the year, there being two rainy seasons.

The climate of elevated regions of hot countries is really the climate of the plains, tempered by that diminution of heat consequent on elevation. There are the same seasonal changes on the mountains as on the plains, and there is the same vertical sun above. No doubt this reduction of heat is a great gain. But in Africa there are no elevated plateaus of sufficient height. To obtain a mean temperature of 51° such as of London, it would be necessary to ascend 10,000 feet in any country, where the mean temperature of the sea-coast is 80°. Stanley was scarcely more than 2,000 feet high during his whole journey, and this is not a sufficient height to afford the advantages of elevation. The lands most favorable to cultivation are the broad tracts which border the rivers and lakes, or, in other words, exactly the places which are most malarious. We are certainly not very familiar with the diseases of Africa, but the following have been noticed: Asiatic cholera, on the coasts at least; beri-beri; dengue; endemic hæmaturia; elephantiasis; guinea-worm; leprosy; malarious fevers; negro lethargy; oriental boil; plague; scurvy; small-pox; tenia; tropical dysentery; tropical diarrhoea; tropical liver abscess; yellow fever; ulcer. This is a formidable list for the European to face, in addition to that anæmia which predisposes him to any disease. There is no doubt that a European possessing the suitable constitution may live long in a tropical climate, and especially in a tropical hill climate if he has no manual labor to perform, and if he takes care of himself. But this is not the question? The query is, can a locality be discovered, within the tropics, or even for a short distance without, where the European can live and labor, and get his bread as a colonist, and leave a healthy European stock? All experience and analogy tend to show this is impracticable.

#### AN EASY METHOD OF PLUGGING FOR EPISTAXIS.

Dr. A. A. PULLER describes a ready method of plugging the posterior nares, which in his hands is both effectual and easily accomplished.<sup>1</sup> A piece of old, soft, thin cotton, oiled silk, or silk, about six inches square—a piece of an old handkerchief will answer—is taken, and by means of a probe, metal thermometer case, or penholder is pushed “umbrella” fashion into the nostril, the direction of pressure, when the patient is sitting erect, being backwards and slightly downwards. It is pushed on until it is felt that the point of the “umbrella” is well into the cavity of the naso-pharynx.

The thermometer case is now pushed on in an upward direction and then towards the sides, so as to push more of the “umbrella” into the pharynx, and is then withdrawn. The closed end of the sac protrudes well into the pharynx, and its open end protrudes at the anterior nares. The inside of the sac may be brushed with some astringent, such as alum or turpentine.

A considerable quantity of cotton wool is pushed well back to the bottom of the sac in the pharynx. Then, the thermometer case being held well against the packed wool, the mouth of the sac is pulled upon, and thus its bottom is drawn forward, and forms a

firm, hard plug wedged into the posterior nares. The sac may now be packed full of cotton wool, dry or soaked in some astringent solution. The mouth of the sac is tied just outside the nostril, trimmed with scissors, and the ends of the thread secured outside.

In removing the plug, open the mouth of the sac, and, with small dressing forceps, gently remove the cotton-wool bit by bit. If there is bleeding, simply syringe the sac with weak carbolic lotion or Condy's fluid, and repack with clean cotton-wool. If there is no bleeding when the wool is picked out, gently pull out the sac, or if it be adhering to the mucous membrane of the nostril, apply a little warm water, and it may then easily be removed.

By this method no damage is done to the floor of the nose or back of soft palate by strings, etc., no disagreeable hawking, coughing, or vomiting takes place during introduction, and no disagreeable strings are left hanging inside the mouth.

#### LOCAL TREATMENT OF DYSENTERY.

Dr. H. C. WOOD calls attention to the local character of dysentery as usually seen in this climate.<sup>1</sup> It is not a constitutional affection, and should be combated by local rather than general treatment. The ordinary treatment owes much of its influence to a local influence.

In acute dysentery, involving the colon high up, he has found large enemata, containing two or three drachms of subnitrate of bismuth, much more efficient than the exhibition of bismuth by the mouth. When the symptoms are severe, this local treatment may often be preceded with advantage by washing out the colon with large quantities of cold water. He has never used injections of nitrate of silver in acute dysentery, although the effect of the local application of the nitrate in other inflammations of the mucous membranes would justify trial of the remedy. He has seen in one or two cases, large enemata of very hot water injected without affording relief, and believes that hot water enemata are, in their ordinary results, not at all comparable with large injections of ice-cold water.

When the lower part of the colon is affected, the local use of ice sometimes has an almost marvellous effect. The author has seen the whole aspect of a very severe and alarming case, in which the symptoms indicated that the colon was affected high up, changed in a single hour by the continuous use of ice suppositories. While it is not necessary to have the pieces of ice entirely regular in shape, care should be exercised that no sharp edges are left. The suppositories should be rapidly used, one being put into the rectum every three to five minutes, so as to get, for at least half an hour to an hour, the effect of the continuous application of cold.

When tenesmus is very severe, iodoform suppositories are often much more efficient than opium in bringing relief. A remedy which has been from time to time recommended very highly in dysentery, but has not been much used, is ergot; and when the passages contain large quantities of blood, or are nearly pure blood, the extract of ergot would seem to be indicated. Dr. Wood has never used ergot by the mouth in these cases, but has employed suppositories containing twelve grains of extract of ergot and four grains of iodoform,

<sup>1</sup> British Medical Journal, July 16th.

<sup>1</sup> University Medical Magazine, August.

used every two hours until four or five suppositories had been taken, with seemingly, great advantage.

The local treatment of dysentery is not advocated as a substitute for the use of mercurials, purgatives and ipecacuanha, etc., but as a very important adjuvant to the older forms of treatment. Nevertheless, in the author's experience, the effect of local remedies has been more prompt and decided than that of drugs given by the mouth; and in cases of any severity the attack upon the disease may be made from each end of the mucous tract.

#### A CASE OF ANNUAL SHEDDING OF THE SKIN.

A UNIQUE case is reported by Drs. J. Frank and W. C. Sanford.<sup>1</sup> For thirty-three consecutive years the patient has completely shed his entire cuticle and the nails of his hands and feet on the same day of the year, July 24th, and within a few hours of the same time of the day. On July 23d, 1890, he was admitted to St. Elizabeth's Hospital, Chicago, for observation, being at the time in perfect health. The patient's history is briefly as follows:

A miner by occupation, has been exposed to all the hardships of camp life, but has borne them with ease, being well formed, and apparently in perfect health. Skin perfectly normal. Has never had any of the eruptive fevers, and has never required the attendance of a physician. He was born in 1857. On the 24th of July following his birth he was suddenly taken ill, — vomited, became hot and feverish, and in a few hours the entire surface of the body was scarlet-red. Symptoms increased for three or four hours, when they gradually subsided, and the patient was supposed to have recovered; but on the fourth or fifth day following the attack the entire cuticle was cast off, and a few days later the nails of his hands and feet were also shed.

The patient first remembers the shedding in 1865, when the cuticle and nails were cast off while at play. These attacks have been repeated each year on the 24th of July, usually at 3 p. m., and never later than 9 p. m. The paroxysm begins abruptly. Patient has a feeling of lassitude and weakness of fifteen to twenty minutes duration, followed by muscular tremors, nausea and vomiting, a rapid rise of temperature, skin and mucous membrane of tongue and mouth become red and inflamed, and are hot and dry. No perspiration appears after the paroxysm begins until the cuticle is cast off. The acute symptoms begin to subside in from three to four hours, and are entirely gone by the end of twelve hours, with the exception of the redness of the skin which does not return to its normal color for thirty-six hours more. The patient has been delirious three times during these attacks, once for nine days. In his early life the cuticle began to be shed on the second or third day after the symptoms appeared, and was complete by the fifth day; but each succeeding year it takes a little longer, until now it is ten or twelve days before shedding is complete. The cuticle can be detached in large sheets, and he has always been able to remove it from the hands and feet in one piece in the form of gloves and moccasins. The nails are loosened and crowded off in about four weeks after the acute stage.

On the 24th of July, the day following his admission into the hospital, the above symptoms occurred with marked similarity. Careful records of pulse and temperature were taken. Between 3 and 4 o'clock marked constitutional disturbance began, lasting some hours and subsiding. The skin became red, the redness gradually subsiding during the next two days. On the 26th the epidermis of the mucous membrane of the tongue and mouth came off. From July 30th, to August 11th, the cuticle came off from different parts of the body in large masses, from the hands as gloves and from the feet as moccasins. The latter were worn as slippers some days after being shed, to protect the feet. The nails came off later.

#### THERAPEUTIC NOTES.

PRURITUS SENILIS. — The *Deutsche medizinische Wochenschrift* gives the following treatment:

(1) Starch or bran baths once a day.

(2) At night the body should be washed with water at 104° temperature, to which the following has been added:

R Carbolic acid . . . . . 5 i.  
Aromatic vinegar . . . . . 3 vi. M.

(3) A powder should then be dusted on, containing

R Salicylate of bismuth . . . . . 3 iiss.  
Starch . . . . . 3 ij. M.

SANTAL OIL FOR COUGH. — Curtin<sup>1</sup> finds that sandal wood oil often gives relief to the cough in phthisis, catarrhal pneumonia, chronic bronchitis with asthma and influenza. It is given on sugar or floated on water.

NAPHTHALINE AS A VERMIFUGE. — According to Dr. Mirovitch<sup>2</sup> naphthaline is an admirable remedy, not only for ascarides, but for tapeworm. He considers it much more certain and far less poisonous than most of the other vermifuges. For adults he prescribes a fifteen-grain powder, to be followed immediately by two ounces of castor oil. For children the following:

R Naphthaline . . . . . 4) to 7 grains.  
Castor oil . . . . . 4 ounce.  
Essence of bergamot . . . . . 2 drops. M.

For two days before the dose the patient is directed to live on salt, acid and highly seasoned food, then the naphthaline is given fasting early the following morning.

MERCURY FOR GLANDERS. — Gold<sup>3</sup> reports two cases of glanders cured by inunctions of mercurial ointment, twice a day for a month, the patient being kept at the point of salivation. The effect on the mouth was combated with chlorate of potash gargles, and on the body suppurating spots were treated by poulticing, incisions, washing out with solutions of perchloride of mercury, and dressed with iodoform gauze.

OPIMUM SMOKING IN PHTHISIS. — Dill<sup>4</sup> has obtained great improvement in several cases of phthisis by giving the patient tobacco to smoke which has been steeped in a solution of opium. In no case were any bad effects from the opium noticed.

Deaths reported 3,333, under five years of age 2,253; principal infectious diseases (small pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,112, consumption 413, acute lung diseases 181, diarrhoeal diseases 111, typhoid fever 99, diphtheria and croup 87, scarlet fever 37, whooping-cough 35, measles 25, cerebrospinal meningitis 18, erysipelas 18.

From Cambridge New York 25, Brooklyn 7, Chicago and Cincinnati 4 each, Philadelphia, Baltimore and Milwaukee 1 each. From Worcester 1 each, Chicago, Philadelphia and Pittsburgh 6 each, New York 4 each, Washington 2 each, Brooklyn 3, Baltimore and London 1 each. From measles New York 12, Chicago, Brooklyn and Philadelphia 1 each, Philadelphia, Baltimore, Pittsburg, Worcester 1 each, Fall River and Malden 1 each. From cerebrospinal meningitis Cambridge New York, Brooklyn, Wash-

ington and Lynn 2 each, Milwaukee, Worcester, Taunton and Newton 1 each. From erysipelas New York 3, Brooklyn and Boston 2 each, Chicago 1.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 25, 1891, TO JULY 31, 1891.

Leave of absence for twenty days, to commence on or about August 5, 1891, is granted Surgeon CURTIS E. MUNN, U. S. Army.

Assistant Surgeon JUNIUS L. POWELL granted leave of absence for two months, on surgeon's certificate of disability, with authority for his admission to Army and Navy General Hospital, Hot Springs, Ark.

## AN ARMY MEDICAL BOARD.

An Army Medical Board will be in session in New York City, during October, 1891, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before September 15, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character and moral habits. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a regular medical college, as evidence of which, his diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon-General United States Army, Washington, D. C.

C. SUTHERLAND, Surgeon-General U. S. Army.

## SOCIETY NOTICE.

THE AMERICAN SOCIETY OF MICROSCOPISTS.—This Society will hold its fourteenth annual meeting at Washington, D. C., August 10-14, 1891.

## DEATH.

JAMES E. TOBEY, M.D., of Central Falls, R. I., died July 28th, aged forty-two. He graduated from the Harvard Medical School in 1872, after serving a year as Surgical House Officer at the Massachusetts General Hospital, and began practice in Central Falls, where he has since resided.

## BOOKS AND PAMPHLETS RECEIVED.

"The Motive and Method" of Electricity in Pelvic Intumescence. By Geo. F. Hulbert, M.D., St. Louis, Mo. Reprint. 1891.

Painful Menstruation. The Harveian Lectures, 1890. By Francis Henry Champneys, M.D., F.R.C.P. London: H. K. Lewis. 1891.

Transactions of the Thirty-fourth Annual Session of the Medical Association of the State of Missouri held at Excelsior Springs, Mo., May 19, 1891.

Linear Craniotomy (Miscellaneous Craniotomy) for Microcephalus. By W. W. Keen, M.D., Professor of the Principles of Surgery, Jefferson Medical College, Philadelphia. Reprint. 1891.

The Pathology, Diagnosis and Treatment of Interferential Growths. By Philip Commins Knapp, A.M., M.D. Fiske Fund Prize Dissertation No. XII. Boston: Rockwell & Churchill. 1891.

The Function of the Tubercle. The Inter-brain: Its Relations to Thermolaxis, Polynosa, Vaso-dilation and Convulsive Action. Two papers by Isaac Ott, M.D., Easton, Pa. Reprints. 1891.

A Pathological Condition of the Lungs Hitherto Undescribed in this Country, but which is not Infrequent. By E. Peyre Pucheran, A.B., M.D., one of the Physicians to the City Hospital, Charleston, S. C. Reprint. 1891.

A Clinical Text-Book of Medical Diagnosis. By Dr. Oswald Viereck. Translated, with additions, from the second enlarged German edition, by Francis H. Stuart, A.M., M.D. Numerous colored and wood engravings. Philadelphia: W. B. Saunders. 1891.

## Lecture.

### NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

(Continued from No. 6, page 128.)

*The Sense of Effort, and Discharge of Energy in Attention.*—A further development of symptoms may follow if the patient continues in a neurasthenic state. While the action of spontaneous attention is always without a sense of effort, as in its passive exercise in reverie which may be restful, it may on the other hand when concentrated, as in continued worrying, be accompanied by expenditure of energy and cerebral exhaustion. Hence the maxim that worry is worse than work. But voluntary attention is normally accompanied by a discharge of energy and a sense of effort. The feeling of effort is at a minimum when the body is strong, but with increasing fatigue the sense of voluntary effort grows greater because more is needed to accomplish the same result as before. This of course is attended by a conscious sense of mental inadequacy through a sense of resistance to effort, which, added to the feeling of physical inadequacy already existing and accompanied by painful emotion, increases the force of self-depreciation. There is deeper depression, more intense worry, increasing cerebral exhaustion, and lessening mental control by will and attention.

*Correspondence of the Train of Mental and Physical Events in Neurasthenia.*—The preceding analysis of these conditions shows what may be the train of concomitant and increasing disturbances of nutrition:—there is local and then general inanition and irritating auto-intoxication,—then vaso-motor constriction, perhaps from irritative elements in the blood, and local or general anæmias,—or a vitiated blood-supply that does not nourish,—or again a hyperæmia from which we may infer a constriction-paralysis, in a condition manifested by a temporarily increased activity, and mental facility which is still a manifestation of inhibitory weakness. Thus a process beginning in the general organism, perhaps with disorders of digestion, may lead by a sequence of events to such results as these. The causes continuing, or being renewed after partial recovery, which may happen many times in a single case, the descent to graver degrees of exhaustion in melancholia may be accelerated by insomnia. This, we have to infer, is due to a hyperæsthesia from weakness and toxic irritation of the central mechanism.

The process may begin with an earlier event:—through necessity or mistaken zeal the individual overexerts his brain in mental work under the spur of interest and forced attention. Here is indeed purely mental initiation of cerebral exhaustion which may start the train of events even in a strong man. Then with an over-worked brain, and under-worked respiration and muscular movements, as in sedentary habits, the cerebral waste of tissue is increased and the nutrition is diminished, by both local and general conditions. Such a special condition, for example, as the uric acid diathesis may be engendered by deficient elimination. From a cerebral neurasthenia all the other events may follow. In this form, however, there may be failure

of special functions, as of memory, for example, in some of its elements. A not infrequent symptom is forgetfulness of names and words,—the fatigued word-memory centres are slow in recalling, or the word-uttering centres are slow in acting, and there are symptoms of brain exhaustion with a hesitation of speech that is unduly alarming. The mental work of a physician or a lawyer is a good example of a peculiar strain of these central mechanisms. There is the daily continuous effort of listening to the details of medical cases, or to evidence and pleadings in some important cause, often followed by work at late hours. It is not strange that there should be a consequent condition of special fatigue of the attention and memory.

*The Unity of Condition in Neurasthenia and Melancholia, etc.*—The essential elements in all cases is, that the fact of a profound deterioration of nervous energy in the organic basis is represented mentally as a more or less vague sense of failing power, together with a conscious reduction of mental control. This is true alike for neurasthenia and melancholia, as has been shown.

Alienists have long recognized these morbid states as associated with variations of nutrition and as fundamental to melancholia, hypochondria, and other like disorders.

Meynert<sup>50</sup> believes melancholia to be a symptom of disturbance of nutrition of the cortex of the hemispheres dependent upon diminished blood supply. Benedickt<sup>51</sup> believes the neurasthenia is a psychic disease of cortical origin, due to emotion and overstrain, and that it is peculiar to the learned professions and business demanding trained, alert intelligence. Marcus<sup>52</sup> describes neurasthenia as a change in the functional tones of the whole central nervous system, with increased excitability and tendency to exhaustion. The patient is always depressed on account of his incapacity, which leads to doubt, anxiety and hopelessness, with a feeling of inadequacy to ordinary effort. These patients are neurasthenic, he says, before becoming insane.

Thus it is to be seen that the neurasthenic condition, being dependent primarily upon nutritional weakness and presenting a train of definite mental symptoms, may, when once established, grow worse by degrees even to the profoundest melancholia, in which the same physical conditions and the same mental symptoms, from like causes as in neurasthenia, are present as a part of the characteristic group of symptoms. It may be said, as Beard tried to show, that neurasthenia is not melancholia, but it cannot be said that melancholia is not neurasthenia. Many cases called neurasthenia are as truly mild melancholia. It is a matter of the degree of exhaustion; in the graver degrees new symptoms are added. Further evidence of this is to be seen in the study of the intellectual symptoms in still more profound degrees of exhaustion. But it is already evident from these considerations that, in all these conditions, the symptoms are dependent primarily upon changes in the organic basis of the personality.

*Definition of Neurasthenia.*—A summing up of the conditions that furnish the clinical manifestations of melancholia would include those of neurasthenia and more. The study of melancholia, as has been said, is therefore instructive as revealing the import of the

<sup>50</sup> Wiener Med. Presse, June 6, 1889.

<sup>51</sup> Medicine Moderne, Feb. 5, 1891.

<sup>52</sup> Allgem. Zeitsch. f. Psych., xiv, 387, 1889.

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.

milder manifestations in neurasthenia. The common conditions of nervous weakness and irritability, and of the special weakening of the attention and mental depression, have been sufficiently noticed. But one other prominent condition should be taken into account in the definition of neurasthenia. The physical lassitude and languor, and motor weakness, pointed out by Bruntton as suggesting curare-poisoning, has its counterpart also in the condition often observed in melancholia and characterized as mental stupor which it simulates. The definition of neurasthenia, properly extended to include the more prominent manifestations, both mental and physical, may be stated as a *morbid condition of the nervous system, the underlying characteristics being excessive weakness and irritability or languor, with mental depression.*

*Cerebral Neurasthenia, and "Insistent and Fixed Ideas."*—Cerebral neurasthenia being once established the general form is then usually developed; but the first may exist by itself, as has been shown, and be of long standing in a healthy organism. The same is probably true of spinal neurasthenia. This central affection is likely to involve, directly or indirectly, other co-ordinated mechanisms. An acute neurasthenia may be rapidly developed by mental shock or the like; it is as if, by a great discharge of energy, the brain cells are quickly brought to a state of exhaustion with inability to perform fully their function of taking up nutrition, or to act in their normal and habitual associations, because of being "thrown out of gear."

A unique form of cerebral neurasthenia may be brought about by the affections known as "insistent and fixed ideas." These are often started accidentally as uncorrected associations of ideas and feelings, and being at first purely disorders of ideation they become fixed by habit and intensified by accompanying emotions usually painful, and sometimes engender great worry and anxiety, because the patient is conscious of his inability to control his own mind against the ideas he knows to be absurd. The worry in these cases may cause a true cerebral neurasthenia. There is a special form of these "fears" that is the most likely to lead to a true melancholia in cases in which there is a strong body with a tired brain,—it is the fear of heredity, when based upon a fixed idea that may have some appearance of truth and cannot be corrected as being absurd. Then the worry is increased both by habit and fatigue. In general it should be said that "insistent and fixed ideas" are primarily accidental disorders of ideation, often occurring in the strong but more likely to happen to the weak. They are the cause of neurasthenia quite as often as they are a symptom of it. The morbid association being once formed, it becomes fixed by habit, inducing or increasing the cerebral fatigue, and constituting an association psychosis, or more properly an association psychoneurosis. When these affections are better understood, an explanation will probably be found for much that is now called hysteria, the neurinosis, etc., including, in the insistent associations, other feelings than fears, that occupy the attention.

#### *Secondary, Chronic, and Hereditary Neurasthenia.*

—The terms of neurasthenia so far discussed are those that are acquired, acute and primary. Secondary neurasthenia, or the form occurring after other definite disease, often not nervous, must be regarded as belonging to the class having special toxic causes. The poisoning may be direct, and sometimes recurrent, as

in the specific constitutional diseases, due to, or inducing, nutritional and degenerative disorders, such as gout, rheumatism, syphilis, etc. Or it may be indirectly due to such diseases as puerperal fever, typhoid fever, etc., in which it may be inferred that, although the toxic materials have passed away, a process of inanition once started persists, or continues to develop. Chronic neurasthenia has already been characterized, and includes conditions of partial recovery, in which a "constitutional predisposition" is fully acquired and established. This is consistent with periods of partial efficiency and comfort, with lessened reserve energy.

Hereditary neurasthenia, as a transmitted predisposition, is a usual cause of localized neurasthenia in special systems or organs. In these cases and in those with a general neuropathic condition, often inherited, there is a tendency to all forms and degrees of neurasthenic disorder, for the reason that, it being a condition of nervous instability and weak resistance, the organism yields to slighter degrees of stress than in ordinary states. The nervous equilibrium becoming unbalanced by slighter causes the departure from the general habitude of the individual is less, and restoration to it easier, than when the normal resistance is great and the break-down is a greater change. When a strong man breaks down it may therefore be more difficult for him to get well than for one less robust and stable. When there is such a predisposition, however, the prophylaxis should be more diligent against neurasthenia and mental disorders. It should be remembered also that in these neuropathic cases one may inherit a strong brain and a weak body, and *vice versa*.

*Symptoms.*—The symptoms of neurasthenia, being manifestations of weakness of the nervous system, proceed from variations from the normal condition of nerve-cells,—molecular and chemical, not yet demonstrably pathological, and implying a weakened or changed nutritional power. The vascular changes—the cerebral and spinal hyperamias and anemias—are due to disturbances of the inhibitory vaso-motor centres. As Dana says, "Neurasthenia is primarily cellular and secondarily vascular." Local anemias may be initiated by an irritative blood-supply,—the vaso-motor constriction starting the deficiency of nutrition in the nervous centres; we may infer that this leads sometimes to hyperamias, just as digitalis first stimulates the cardiac inhibition, and then by overstimulation and a toxic effect paralyzes it.

The fundamental and initial condition being thus a weakness of nerve-cells from excessive waste and deficient repair, to which there is a toxic addition to the "fatigue," then two types of symptoms must be recognized,—those characterized by a too quick response to stimulation, due to "irritability" or hyperaesthesia, and those due to a slowing or annulment of functional power, manifested by "languor," or even a complete suspension of function. These conditions of abated power, with "irritability" or "languor," occur in different degrees, and are common to the sensory, central and motor parts of the mechanism; they often affect one part more than the others, according to the localization of the "fatigue," or the kind of toxicity. The symptoms of neurasthenia are mainly subjective.

The objective symptoms may be first considered, by noting the common physical conditions. There is a general appearance of abated vigor, bodily weariness, languor and mental depression, and loss of weight.

There is not necessarily anæmia, but this is common in young persons and women; it is not present in many adults who may be physically well-nourished or plethoric. There may be tremor of the hands, sometimes only following muscular effort or mental excitement. Uneasiness, restlessness and excessive irritability are also common.

Loss of vaso-motor tone is indicated by cold hands and feet, and the temperature is often sub-normal in the more exhausted cases. Morbid blushing is common in nervous exhaustion in both sexes, from slight mental or physical causes. A characteristic form of the blushing is that which occurs in patches upon the neck and cheeks, of a bright color and with well-marked borders slowly spreading. This may appear with only the effort and interest of an ordinary conversation. The disturbances of the circulation are marked by cardiac palpitations, and the phenomena of an "irritable heart." The pulse shows frequent and rapid variations in arterial tension; it may be reduced in frequency with increase of tension, or be more frequent and weaker, and often quickly accelerated by exertion or slight emotional excitement.

Dilatation of the pupils is a common symptom, and may be due to paralysis of the third nerve or irritation of the sympathetic. These suggest nervous weakness, irritability and perhaps different toxic influences. A striking peculiarity is a quick and frequent alternation between this and contraction. The atonic voice is peculiarly significant, — it is faint and husky, and frequently varies in force. Sometimes it will suddenly change to a higher pitch and sound thin and weak. Respiration is not changed in frequency, but deficient respiratory expansion may be observed, with the symptoms of compensatory sighing and yawning.

The appetite is poor; there are disorders of gastric and intestinal digestion, gastric irritability with atonic dyspepsia, and constipation, sometimes alternating with nervous diarrhoea; and flatulence with feelings of distension; there is gastric neurasthenia, and a "torpid" or "neurasthenic" liver, and the important toxic consequences. Elimination generally is greatly at fault, by liver, kidneys and skin. The urine varies in specific gravity, being usually low in younger persons, with phosphates in excess. Older persons have more digestive and hepatic disorder, and a condensed urine with sometimes excess of phosphates, urates, and oxalates. Traces of albumen and casts are common in the depressed cases, as in melancholia. The peculiar symptoms of "uric-acidemia" are so common in neurasthenic conditions that a careful study of this toxic element is likely to be profitable.

Neurasthenic irritability of the bladder and urethra occurs in both sexes; and in women the lowered nervous tone is manifested in menstrual disorders. While amenorrhœa occurs, particularly in the graver cases, as in melancholia, etc., it is often physiologically conservative; there may be an increase of the flow, and even the ordinary amount, in anæmic conditions, becomes relatively a hæmorrhage. Many such cases are kept indefinitely in a state of exhaustion by losing monthly all the upbuilding they can gain. Irregular menstruation and dysmenorrhœa are also common. Women in general suffer more than men from sensory and irritative symptoms, — there is more pain, headache, and neuralgia, and the complications of hysteria occur. The diseases peculiar to women may be either the causes or effects of neurasthenia. The symptoms

of sexual functional disorders, generally, should always be first studied carefully, as probably expressions of a general neurasthenia. This is true also of the disorders peculiar to adolescence and the climacteric, — at the latter period of life men also are prone to neurasthenic troubles.

Insomnia has already been especially noticed as a symptom of irritability, — a cerebral over-excitation from local irritation, or that condition initiated by intensified interest and attention until the symptoms of "fatigue" supervene. Macfarlane defines insomnia as an evidence of vigilance in the cerebral cells, initiated and maintained by some perturbing element in the system, of which it may be the sole symptom.

The *subjective* symptoms are thus broadly characterized for convenience, as those of which the patient himself gives account. This division from the objective symptoms is open to criticism; the thesis of this discussion is, in part, to show that the inner conditions are largely revealed by mental symptoms which are obvious to the clinician who obeys Kraft-Ebing's injunction to pursue an untiring observation of the physical processes. While the patient may describe his feelings and tell his thoughts, in their subjective aspects, the clinical observer sees the plain and often contradictory significance of the patient's unwitting expressions of mental phenomena that are objectively manifested in his appearance and conduct. The physician, taking into account all the data, solves paradoxes and makes interpretations, that the patient cannot make of what he feels and seems to perceive. It is a part of the present purpose to make clear some of these apparently conflicting indications.

The study of the symptoms of neurasthenia means, then, the observation, and the careful analysis and discrimination, of the physical signs on the one hand, to differentiate them from the manifestations of more definite nervous diseases which are so often simulated in this disorder. We have, on the other hand, with these observations as guides, to discriminate in like manner the mental signs as expressed in the patient's appearance, conduct, and speech. The subjective symptoms are, therefore, of two kinds, — what the patient tells of his bodily sensations and mental feelings, and of his ideas of them, and what he manifests otherwise as expressions of his mental condition. The business of a physician is to make an interpretation of these phenomena, consistent with physical facts, and to give his patient treatment that is often as much of the mind as of the body.

The first and most obvious mental signs, taking the evidence from both of the sources just specified, are the characteristic depression of feeling, — lowering of emotional tone and a sense of ill-being. Coincident with these, but derived more from the patient's own statements, are a decrease of the power of voluntary attention, — attention becoming reflex, — and sometimes decrease of the power of memory in its elements of retention and recalling, and in the association of ideas. The first order of these symptoms represents, in the changes of emotional tone, etc., the concomitant changes in the organic personality, — the patient speaks despondingly and appears dejected, — he has "the blues." The second order shows, in the lessening of mental activity and inhibitory power, the abatement of cerebral energy, — the patient becomes conscious of this because of the increased sense of effort, and he may tell of it before it can be observed by

others. The sources and "mechanism" of these two orders of symptoms have been shown.

A third order of symptoms proceeds from the first two, as has been shown; it is somewhat later in appearance and marks a graver degree of nervous exhaustion. It includes introspection, or dwelling by attracted attention upon anxieties or painful ideas, intensified by the prevailing emotional tone,—retrospection, which is a constant and striking symptom in those who, from a sense of inadequacy, lose hope and therefore *interest* in the future, and find it in the reviewing of past experiences, errors or wrong doings,—and apprehension, as sometimes a feeling of hopelessness, or vague fear of inability to meet the requirements of the future or the consequences of the morbidly intensified memories of past misdeeds. These constitute the condition of worry and hypochondria.

All these orders of symptoms are usually present in slight degrees, and coincident at the very beginning of pathological fatigue. Their severity increases with decreasing energy,—from transient "fits of blues" to the most marked forms of the disease. When the condition continues, reasoning is likely to be soon influenced by the bias of morbid feeling, and the law of practice, habit and association comes in, tending to fix the morbid "habits of thought" as well as the disorder in the concomitant physiological processes. Then secondary effects begin to demand discrimination, and the force of habit must never be forgotten. For example, a business man, having become neurasthenic from over-work and worry, may attend to his affairs, with excess of application, and feel better doing so, through the effect of habit, and the stimulating effect of attention and interest as excitants of cerebral activity and a quickened circulation. Let him attempt, however, to turn his attention to other matters, as to rational recreation, and his loss of power to control his own mind betrays itself. At the beginning of the attempted relaxation, as in taking a vacation, there is more of mental effort, and of the depression of feeling, than in keeping on with his habitual occupations, though harmful. Or, again, such an experience as that described in a letter from a medical friend, who has had large success in treating neurasthenia, and who contributes unintentional testimony on this point, as follows: "I have been feeling so good-for-nothing and so blue that I have feared almost everything. These 'rheumatics' are not very comfortable companions, and the fear that they might get so bad as to prevent me from riding, has depressed me a good deal. I know that in other ways I am much better than a year ago, but in the past three weeks, when the letting up of work has come, there has also come a letting down of spirits. The work now is not more than one third of what I do when decently busy, but I get very tired when evening comes. I am all played out." It is altogether probable that had not his active season been terminated so soon by the summer vacations, he would have gone on with his work and postponed the onset of his "fatigue" and the return of his annual attack of sciatica,—but doubtless with more serious consequences at a later day.

These cases show the three orders of symptoms, and represent later stages of the conditions noted in the two examples of evening fatigue illustrating the genesis of pathological fatigue. They bear also a curious resemblance to another very common experience:—An occasion of severe mental labor,—perhaps of

night-work and little sleep,—is followed by a day of excitable alertness of mind and body; there is a sense of nervous strain, but with an undue mental facility and physical irritability. But after the next night's rest a sense of fatigue, languor, and *malaise* may come—the second-day tire that leads to the inference of the elimination of an irritating stimulation revealing the real fatigue. In cases of neurasthenia, at more advanced stages, from long-standing or a more rapid development, the effects of habit upon the disordered physiological and mental activities become more pronounced. New symptoms also appear, due to greater changes in the nutritional processes, and particularly in the sensory mechanism.

The three orders of symptoms described refer to strictly mental phenomena and contain no mention of the irritability and languor common in this disease. These latter symptoms are both mental and physical, and they are direct manifestations of changes in bodily conditions. They now remain to be characterized as constituting a fourth order. We have, therefore, to examine further the subjective symptoms in respect to altered sensations. They include both those from the special senses and the largely predominating organic sensations. They may be distinguished as hyperæsthesia, paræsthesia, and anæsthesia.

*Hyperæsthesia* may be held to include all the phenomena of excessive irritability. It may be sensory or motor, or central and mental. General morbid sensitiveness is manifested by "nervousness" and restlessness; the patients, especially women, have a sense of "tension" and difficulty of self-control. There may be irritative and neurasthenic conditions of all the organs and minor mechanisms. The local hyperæsthesias are very many—as of touch, in which however there is no real increase of delicacy, but almost always a diminution. In many cases the commonly unperceived organic sensations are intensified. The sense of pain belongs to this group of "common sensations," and they include the neuralgias along with which there may be a duller perception of tactile impressions. Itching, burning, and other conditions bordering on pain, are included in this group of sensations that differ from the tactile sense.

Sensitiveness to ordinary stimuli in the organs of special sense, particularly of sight and hearing, is common. The visual troubles are not very serious, but there is always some weakness and increased irritability. Reading causes fatigue and pain and leads to headache; and there is sensitiveness to light. Muscular insufficiencies occur. Visual memories are lessened. The hearing is over-sensitive in many cases, and the patient is very intolerant of slight noises. This may be due to the general mental irritability, and to expectant attention. These neurasthenic symptoms may be continued after recovery as the effects of mental habit. Hyperæsthesia may be regarded as the first degree of sensory disorder and weakening.

*Paræsthesia*, or perverted sensation, may be considered as representing a second degree of sensory disturbance and change from normal feeling, and may be general or local. Internally these disorders include giddiness, vertiginous sensations, a sense of muscular relaxation, etc. According to Gowers, the afferent impressions constantly passing to the cerebro-spinal centres, fail to affect consciousness under normal circumstances. But repeated attention may vastly increase the sensitiveness of the perceptive centres to

such impressions, and from such increase arise sensations of great discomfort, sometimes amounting to pain. In the case of an intelligent lady whose conscientious efforts to disregard her ills stamped the description as genuine, there was, at times, for many months, a feeling "like a stream of pounded glass running down the spine into the pelvic cavity." There may be perversions of the peripheral sensations, as pressure on the top of the head and of a band about it, a sense of expansion of the skull or as if it were empty. Feelings of flushing, both local and general, may occur, and numbness and coldness as alterations of the temperature sense, etc., in different parts of the body. This and the sense of pressure are to be distinguished as special functions, differing from tactile sense. Creeping sensations, tinglings and formication, are common among the paræsthesias.

*Anæsthesia* is the final degree of changed sensations, and may be partial or complete. For example, numbness of the hands and feet is not uncommon; and there are limited anæsthesias of the tactile sense in various parts of the body, or this being retained, there may be analgesia as simply the loss of the sense of pain. The lowering of sensory activity in general, or diminished sensitiveness, has been observed. This is common enough to demand recognition as one of the characteristics of neurasthenia along with "excessive irritability;" in both alike there is probably a toxic influence, or its secondary effects. There may be limited areas of anæsthesia or hemianæsthesia, particularly in hysterical conditions, although "hysteria is essentially a mental disease involving the emotional functions and the will."

The importance of these altered sensations is very great for their diagnostic value and as a guide to treatment in neurasthenia. Such disorders of the sensory apparatus of the special senses, as is well known, lead to the illusions and hallucinations, or disorders of sense-perception, in the graver degrees of the exhaustion of melancholia and mania. But the organic or common sensations are of fundamental importance, for, according to Ribot, "As the organism, so the personality." Taking the evidence of our bodily feelings, the sense of physical personality is the organized and co-ordinated sum of its elementary factors. Persisting alterations of organic sensations and aberrations of the physical personality, or as Bertrand calls them, "the hallucinations of the sense of the body." A man believes himself to be what he feels himself to be. He finds in the evidence furnished by the sum-total of his feelings the data for his judgments of himself. These sensorial alterations are doubtless expressions of more deeply seated disorder due to localized and limited derangements of the circulation. A limited central exhaustion and excitation may be accompanied peripherally by vascular irritability and disturbance.

The relation of these altered sensations to their mental effects has been considered, and something has been said of the converse effects of mental states, as to the emotional tone and attention, upon the physiological activities. The mutual influence of mind and body upon each other is of great importance here, as to the causation of the conditions manifested by these changes in the organic sensations. Mosso has demonstrated that hyperæmia of the brain is coincident with mental work. It is physiological that centres becoming inactive resume a normal and comparatively anæmic state. The removal of the excess of waste

that attends activity being accomplished by due periods of rest, the centres recover their normal condition, and work may be resumed on awaking from sleep. With over-work of the brain, and prolonged and probably localized hyperæmias, the exhausted vaso-motor apparatus becomes unable to control the blood-supply; local and relatively chronic hyperæmia in the over-exercised centres may follow and become pathological. In this state work may be continued by voluntary effort, but there is sleeplessness, and breaking down of the general health. The exhausted and poisoned brain, and nervous system generally, afford only a defective innervation to the various organs of the body; and the characteristic symptoms of dyspepsia, constipation, palpitation, and the like, appear, with all their sequelæ of altered sensations.

Macfarlane<sup>53</sup> describes the symptoms of this condition of neurasthenia as tolerably uniform, — sleeplessness being one of the most urgent, usually associated with throbbing blood-vessels and restless cerebration, dreams connected with the daily work, and the sleep obtained being disturbed and unrefreshing. The element of worry has been shown to be a prime factor in all these neurasthenic conditions. It is especially noteworthy that Macfarlane mentions certain symptoms of present interest, — they are the most prominent signs of the earlier alterations of cænesthesis so well studied by Ribot. The former says, "Exhaustion and misery are felt in the morning; depression, despondency and irritability during the day. All mental and physical work is accomplished with an effort, concentration of thought is difficult, and headache is seldom absent."

### PERSONAL OBSERVATIONS ON THE PATHOLOGY AND TREATMENT OF NEURALGIAS OF THE FIFTH PAIR.<sup>1</sup>

BY JAMES J. PUTNAM, M.D.

The subject of trigeminal neuralgia still presents, in spite of its enormous literature, many points of interest and uncertainty to the pathologist. What is the real cause of the pain? What gives the attacks their peculiar form, their tendency to recurrence, to abrupt disappearance and reappearance? What common factor can we find in the many modes of occasionally successful treatment? All these are questions which still press for an answer.

The main object of the present communication is to report the results of the microscopic examination of a number of nerves removed by the surgeons of the Massachusetts General Hospital,<sup>2</sup> and to indicate as far as possible the lines which I think we should follow in treatment. Before referring to my own observations, I wish to clear the ground a little by indicating the forms and the general conditions under which neuralgia of the fifth pair is liable to occur.

The nucleus of the fifth runs the entire length of the medulla and pons, and, with its descending root,

<sup>1</sup> Read before the Boston Society for Medical Improvement, March 23, 1891.

<sup>2</sup> In this connection I desire to express my thanks to Drs. J. C. Warren, M. H. Richardson, A. T. Cabot, John Thomas and S. J. Myster for their co-operation.

<sup>53</sup> *Op. cit.*, pp. 78-82.

almost the entire length of the aqueduct of Sylvius as well; and this doubtless indicates an enormous wealth of connections with other nerves, and a corresponding exposure to the morbid influences originating in disorders of distant parts of the body.

Of these so-called reflex neuralgias, so well described by Dana,<sup>3</sup> and by Ross,<sup>4</sup> it is not my intention to speak at length, but only of those originating within the domain of the fifth nerve itself, and more especially of that form commonly known as *tic douloureux* or *epileptiform neuralgia*.

The exquisite sensibility of the face, lips and tongue indicates a high degree of excitability on the part of the central apparatus of the fifth pair; and it is doubtless this excitability—which when it becomes morbid we term irritability—that gives this peculiar character to the outbreaks of violent pain with which we associate the names of Fothergill and Tronseau. Lightning-like pains are, to be sure, met with in other forms of neuralgia to some degree, but they form the peculiar characteristic of the trigeminal neuralgias. The cases in which these occur are often set aside as forming a special group; but I think it is a truer expression of the facts to say that neuralgia of the fifth, especially of the two lower branches, when it becomes severe, almost always takes on this form, while in the lighter forms the pain may be duller and more continuous. It is not alone the cases of well-marked neuritis that are epileptiform in type. Instances are on record where the neuralgias set up by such general causes as shock or fright have been of this character. Gowers gives the case of a young lady which originated in this way; and I have known a similar form to come on immediately after a railway accident, in an adult man. As a rule, neuritis is present; and it probably exists far oftener than we think, and forms a partial or predisposing cause of the neuralgic outbreaks.

As regards the representation of the fifth nerve in the cerebral cortex, we know, so far as I am aware, nothing definite; but the interesting fact may be noted that in migraine, which, so far as the pain is concerned, is a neuralgia of the fifth nerve, many cerebral symptoms are present, largely visual in character, but including also aphasia, mental depression and the like.

Dr. Weir Mitchell has called attention to the fact, that instead of the simpler disorders of vision which are so common in migraine, hallucinations of analogous character may occur. It is true that the prevailing opinion refers the pain in migraine and headache not to the primary affection of the fifth pair, but to some distant irritation or to a disorder of the vasomotor system and the like. I desire, however, to call particular attention to the fact that one form of trigeminal neuralgia at least—that of the supra-orbital division—is closely related to migraine and the periodical headaches, and yet is often associated with neuritis.

The neuralgias of the ophthalmic division certainly show a distinctly different tendency from those of the second and third division.

I have already noted the fact that the so-called epileptiform neuralgia is more common with the latter nerves. It is occasionally seen in the supra-orbital region, but much less often than in the lower part of the face. On the other hand, supra-orbital neuralgia

is usually so typically intermittent,<sup>5</sup> with distinct daily occurrences, that it used to be considered as malarial, and was called "brow ague"; and, in fact, it is still spoken of in that way by various writers, especially when it occurs in malarial districts. This notion is no doubt strengthened by the fact that this form of neuralgia almost invariably yields to large doses of quinine given three or four hours before the time of the expected attack.

I am glad to see, however, that Dr. Mitchell, in a recent paper, takes a decided stand against the supposed malarial origin of these neuralgias, which, for this neighborhood at least, where supra-orbital neuralgias are sufficiently common, is certainly out of the question. Usually these intermittent headaches or neuralgias are immediately called out by catarrhal inflammation of the frontal sinus, to which the supra-orbital nerve supplies sensory fibres; but they are by no means always provoked in that way, and even when so provoked it is probable that the sinus irritation acts by exciting a neurosis for which the nerve centres were already prepared. If this is the case, as I fully believe, it only shows the artificial character of the distinction which we try to draw between the so-called reflex neuralgias, and those due to irritation or inflammation of a peripheral nerve in the distribution of which the pain is felt.

Even in this case, where the pain is felt in the distribution of an inflamed nerve, and even though the neuritis or peripheral irritation is a *sine qua non* of the attack, the factor which gives the neuralgia its distinctive character is usually the special morbid condition and the constitutional and physiological peculiarities of the nerve centre, and so the neuralgia is, strictly speaking, "reflex." Conversely, I believe that every neuralgia, even if of "central" origin, or provoked by some distant cause, is liable to set up neuritis, provided the pain occurs often enough and lasts long enough in the same area; and that this is one of the many ways in which influences acting on the central nervous system, such as fright or other strong and painful emotions, or trauma, or general anæmia, join hands with influences directly setting up gross organic changes.

Supra-orbital neuralgia, even if peripherally provoked, is often hereditary, is sometimes closely related to migraine, is liable to show itself from childhood on, and is said to have, with some persons, a tendency to recurrence in spring and autumn, the attacks lasting two or three weeks. The pain almost always appears each morning from seven to nine o'clock, and disappears about two, perhaps to return again in some degree in the evening. It is, now, noteworthy that this intermittent headache is liable to become complicated with a distinct neuritis of the supra-orbital nerve. I know one such case intimately, where the neuritis produced trophic changes in the skin and the sub-cutaneous or periosteal tissues of the forehead. And this was one of the cases where the supra-orbital neuralgia was hereditary, was associated with migraine attacks, occurring in the same patient and in others of his family, and had begun in childhood, when, to be sure, the neuralgia never occurred without being preceded by irritation in the frontal sinus. After a time, perhaps only after the

<sup>3</sup> *Medical News*, March 19, 1889.

<sup>4</sup> *Brich*, January, 1888.

<sup>5</sup> Compare Schweick (Wochehschrift für die ges. Heilkunde, 1848, xvi, 2), Mönster (Neuralschrift für die Pract. Heilkunde, Prag, 1847, B. 119), Seifert (Berliner klin. Wochehschrift, 1881, xviii, 138). The latter gives also reference to other writers.

establishment of the neuritis, the outbreaks of pain became less markedly dependent on catarrh of the frontal sinus, and lost a little, though by no means the whole, of their periodic tendency, coming on after fatigue and from exposure to damp cold.

In this case, as in others of the same class, the eye of the same side became weaker, probably from slight neuritis of its motor nerves, so that, even after a number of years had passed without anything more than a trifling amount of neuralgia, it remained more liable to painful fatigue than its fellow.

An eminent French neurologist has told me that he had suffered some degree of permanent impairment of visual acuteness in one eye from the same cause.

An interesting series of observations has recently been published by Thoma,<sup>6</sup> in which he refers to the general fact that congestion, in general, is liable to lead to endarteritis of the vessels involved, and records investigations of his own, showing that this seemed to occur over the affected area in a case of supraorbital neuralgia. In this way, perhaps, a neuritis might be set up or intensified.

The tendency to periodic recurrence, so characteristic of supraorbital neuralgia, is met with, to a less degree, among the other neuralgias, both of the face and elsewhere, especially, it is said, the traumatic neuralgias. I have no explanation to offer for it, beyond the suggestion that the recurrence of the "brow ache" in the morning may possibly be related to the reawakening of cerebral activity. Most persons who are subject to migraine are apt, I think, to wake with an attack.

The relationship between true migraine and supraorbital neuralgia is further shown by the fact that persons who suffer from the former disease are sometimes liable to have attacks of supraorbital and occipital neuralgia with marked tenderness of the affected area.

Before leaving this subject of the neural relationship between peripheral neuralgia of the fifth pair and the periodical headaches, I would note the fact that mental symptoms, by no means due solely to pain, may complicate the cases of pure neuralgia, forming an evidently "central" symptom. In one of the cases of supraorbital neuralgia above described, the attacks were sometimes preceded, but not necessarily accompanied, with a feeling of well-marked gloom, recalling pre-migrainous symptoms.

As regards the pathological anatomy of the neuralgias of the trigeminal, we know as yet, so far as I am aware, only the changes that occur in the nerve-trunks. It was a favorite theory with the late Dr. Austie, of London, — by whose zeal, intelligence, and industry we owe much enlightenment on the clinical sides of this subject, — that an atrophy of the ganglionic spinal nucleus was the real cause of the neuralgia. The hypothesis was unproved, and has generally been referred to only to restate that fact. The general tendency has been to regard neuralgia as one of the neuroses, but of late years, under the impulse of the increasing confidence in anatomical research, physicians have turned more and more away from the neural or, so to speak, central aspect of neuralgia, and have looked with more and more favor on the view that, in the chronic forms of neuralgia at least, the pain is simply the expression of the inflammation of a nerve.

There is much to be said on both sides of this controversy, but the recent discovery that the physiological

activity of nerve-cells leaves its impress on the cell in the form of demonstrable changes in the size and shape of the nucleus, would, even without other evidence, make it nearly certain that sooner or later, actual changes of more or less gross character must take place in the central nervous system as a consequence of these repeated and violent storms of pain. Moreover, as a matter of fact, the hyper-irritability, or impaired storage power of the nerve-centres, is a condition with which we have always to reckon in the treatment of neuralgia. A neuritis, if present, may have to be got rid of before this morbid condition of the nerve-centre can be cured, but this is not always necessary, any more than it is always necessary to get rid of a uterine retroversion in the treatment of reflex nervous symptoms due to that cause. Indeed, nothing is more striking than the fact that a change in the hygienic surroundings of a patient, both moral and physical, may make all the difference of his reacting or not reacting to a peripheral irritation, and one of the most marked features in the history of the trigeminal neuralgias in particular is the occasional disappearance, spontaneous or under treatment, of a severe attack of pain, in spite of the persistence of its apparent peripheral cause. Such a disappearance of pain gives absolutely no warrant for the conclusion that neuritis, even of a high degree, is probably absent.

The anatomical changes in the nerve-trunks, in trigeminal neuralgia, are better known and more striking than those in the nerve-centres, and are sometimes recognizable even by the naked eye. Thus, in a case reported by Tuffier,<sup>7</sup> of neuralgia of the lower jaw in a man of eighty-four years, the nerve was found swelled and reddened, both within the dental canal and before its entrance, and histological examination of the teased nerve in osmic acid showed diseased and healthy fibres side by side. Gross changes of this kind have not been recognized in any of the specimens that I have examined, and, to judge from published accounts, they must be rare.

As regards histological changes, Dr. J. Ewing Mears,<sup>8</sup> of Philadelphia, has given the report, illustrated with drawings, of a careful microscopic examination by Schweinitz, of an inferior dental nerve, removed for neuralgia. All the changes characteristic of severe chronic neuritis were found, such as I have observed in most of my examinations. These changes involved both the nerve-tubes and the interstitial tissue, and were most marked at the peripheral end of the nerve. Besides this I know of no detailed histological statements, though I have not made an exhaustive search for them. There are, to be sure, a number of cases on record where the Gasserian ganglion, or the fifth nerve in its intracranial course, has been compressed by exostoses or inflammatory products or other morbid growths, but of these cases I will not speak.

In some cases the neuritis is of peripheral origin, excited by disease of the teeth, alveolar process, mucous membranes, etc. It is sometimes said that the teeth should not be blamed as the cause, because the neuralgia so often fails to cease upon their removal, but it is obvious that this conclusion is no more apt than it would be in the analogous case of neuralgia of the stump. In both cases there is a marked tendency of the neuritis to spread, and this may possibly be

<sup>7</sup> *France Médicale*, Paris, 1881, xxviii, 672-675.

<sup>8</sup> *Transactions American Surgical Association*, Philadelphia, 1884, ii; also *American Journal of the Medical Sciences*.

<sup>6</sup> *Deutsches Arch. für Klin. Med.*, 1888, vol. xliii, p. 409.

given by the introduction of toxic substances within the sheath of the cut end of the nerve. At any rate it is certain that, in many cases, the neuritis does spread rapidly beyond the place of its origin and even involves other branches of the nerve.

In other cases the neuritis may be vascular in origin, arising from congestion, perhaps oedema, due to the attacks of pain as such, as suggested earlier in the paper and confirmed by the observations of Thoma.

It is certain that neuritis may be increased, if not actually set up, by the congestion attending an attack of pain — of neuralgia, as we ordinarily say. The suggestion of arteritis as an additional link between the two processes is a valuable one.

This is, I think, an important practical point, as it affords an explanation for a well-recognized clinical sequence. Take, for example, such a case as one reported by Derver,<sup>2</sup> where the irritation due to so minute a lesion as ulceration of the cornea was apparently the starting point of a trigeminal neuralgia which eventually required the removal of all three branches of the nerve. Is it possible that this result would have been, in a measure, obviated if the attacks of pain, with the resulting congestion, could have been prevented? It seems to me that there is a good deal to support this view, and that it indicates the importance of checking pain, not only for its own sake, or for the sake of relieving nervous fatigue or preventing the formation of a habit, but to guard against the strengthening of the vicious circle, of which neuritis is an important member.

FIG. 1.

Conversion of a nerve bundle into nucleated, wavy connective tissue. At B the traces of nerve tubes remain, but they are very small, and apparently without axis cylinders or myaline.

I myself have examined ten nerves coming from eight patients, most of whom were operated on at the Massachusetts General Hospital. More or less marked changes were made out in all but three of these nerves, which seemed, at the points examined, to be substantially normal. The slighter changes, which seemed not to be incompatible with the integrity of the nerve-element, consist in an infiltration of small nerve cells in the nerve sheath, around the vessels, and amongst the nerve fibres themselves, especially in the neighborhood of the sheath. Thickening of the endoneurial septa and of the interfibrillary substance is also common. The

most extreme changes consist in the conversion of the entire bundles into a mass of wavy connective tissue studded with nuclei and scarcely containing a single nerve fibre. This extreme change was present in only one case (Fig. 1).

I examined with especial care the perineural sheath and the blood-vessels, but, although I believe both to be the seat of morbid changes which are likely to be of considerable importance as affecting the nutrition of the nerve, I do not feel myself sufficiently familiar with normal conditions, especially in persons of advanced age, to give a positive opinion.

FIG. 2.

Thickened septum between the fasciculi (A) of a nerve trunk. At B are small bundles of nerve tubes, most of which seem to have been destroyed. The connective tissue contains many cells. At C is a blood vessel. This and the next drawing are on a larger scale than No. 1.

As regards the sheath, it may at least be said that in most of the cases it was very thick and richly nucleated and that it was relatively delicate in others, and, further, that in the latter the other morbid changes were generally less pronounced (Fig. 2).

(To be continued.)

#### OBSERVATIONS ON THE SUPPRESSION OF INFECTIOUS DISEASES.<sup>1</sup>

BY J. H. MCCOLLUM, M.D., OF BOSTON.

(Concluded from No. 6, page 131.)

ANOTHER and still more important expedient for the suppression of these diseases is a careful medical supervision of the schools, not only for the purpose of ensuring good ventilation, but more particularly for the detection of mild cases.

There can be no doubt that many epidemics are caused by the presence of these mild cases in the schools. Chart B shows the total number of cases of diphtheria and scarlet fever, by months, for five years in Boston, comprising an aggregate of 11,794 cases, certainly a number from which reliable deductions can be made. It will be seen at a glance that the largest

<sup>1</sup> Read before the Massachusetts Association of Boards of Health at Newton, April 29, 1891.

number of cases occurred during the months of January, February, March, April, May, June, September, October, November and December, or during the time the schools were in session, while during July and August or in vacation time the cases diminish more than one-half. It is true that during the month of June there is quite a marked diminution; but this can be explained by the fact that at this time there is better ventilation in the school-rooms. It is very significant that during August with an average mean temperature of  $68.02^{\circ}$ , when the schools are closed the number of cases is 540, while in June, with an average mean temperature of  $65.58^{\circ}$ , there are 842, and also that in May, with an average mean temperature of  $57.10^{\circ}$ , the number of cases reaches 1,087, more than twice as many as are reported in August. As the difference in the mean temperature between June and August is only  $2.44^{\circ}$  being  $65.58^{\circ}$  in the former and  $68.02^{\circ}$  in the latter, it is not to be supposed that this slight difference can account for an increase of 300 cases, or in round numbers a fall of one degree in the temperature is responsible for an increase of 100 in the number of cases. If a low temperature has such a remarkable influence on the prevalence of these diseases as has been claimed by some, we ought, on general principles,

CHART B.

Cases of Diphtheria and Scarlatina, by Months for Five Years, with the Average Mean Temperature—1886-90.

Temp. ....

Cases —

to have instead of 1,289 cases in January, 4,000. Again, as is well-known, the schools open in Boston on the first Wednesday of September, and during this month the increase is 100 as compared with the number of cases in August; but there is a still greater increase from September to October, November and December. By following the broken line which indicates the average mean temperature, it is evident that the temperature has no direct influence on the number of cases. This certainly refutes the argument that the low temperature of the winter months is responsible for the increase in the number of cases.

The method adopted in Boston for the suppression of these diseases is: First, a report of the case by the physician in attendance; second, posting of a card on the house notifying the public of the existence of the disease; and in the case of diphtheria examination of the drainage; third, investigation of the case by one of the medical officers for the purpose of giving advice regarding isolation, and the importance of removal to hospital when the case occurs in a tenement-house; fourth, the sending a notice of the case to the school

committee and also to the public library; fifth, the sending of a printed circular to the house of the patient, containing plain and explicit directions regarding isolation and the best methods of disinfection of the clothing and discharges of the patient; sixth, the visitation of the house by the disinfecter, who leaves a postal card addressed to the Board of Health, on which is to be stated when, in the opinion of the attending physician, the premises will be ready for disinfection. In the case of a death as soon as the death certificate is received at the office of the Board of Health, arrangements are immediately made for disinfection. It is, of course, understood that public funerals in these cases are prohibited.

The method of disinfection adopted at present consists in the use of a solution of corrosive sublimate one part to five hundred for washing the wood-work of the apartment, and walls, if painted; in some instances of sponging the mattresses and carpets with a similar solution. The apartment in which the patient has been ill, is then tightly closed and four pounds of sulphur to every 1,000 cubic feet of space is burned in it. In addition to this there is an apparatus for the generation of a certain amount of steam, for it has been proved by many experiments that the disinfecting power of sulphurous acid is much increased by the presence of watery vapor. Without, at the present time, stating the arguments for and against the use of this substance as a disinfecting agent, it is sufficient to say, that during the past five years only two per cent. or 236 of the cases of scarlet fever and diphtheria of the 11,794 reported, could by any possibility be traced to infection from rooms or clothing that had been disinfected in the manner just described. So far as small-pox is concerned, in the 112 cases during the past ten years, where sulphurous acid gas has been the only disinfectant used, there is not a single instance of infection from an apartment in which there had been a previous case.

CHART C.

Percentage of Deaths from Group, Diphtheria, Scarlatina and Variola to the Total Mortality for Ten Years—1881-90.

A study of Chart C, which indicates the percentage of deaths from group, diphtheria, scarlet fever and small-pox to the total mortality in Boston for ten years shows that in 1881 the percentage was 9.35; in 1882, it fell to 7.31; in 1883, it rose to 8.42; from

1884 to 1886 there was a gradual decline until the rate was 5.44; from 1886 to 1889, a somewhat exceptional period, in which these three diseases were quite prevalent throughout the whole country, the percentage gradually increased until it reached in 1889, 6.90; during the year 1890 it fell to 4.95; a diminution of nearly two per cent. in a year, and of nearly five per cent. in ten years. But it might be said by some that although the number of deaths from these diseases may have diminished, the number of deaths from other zymotic diseases has increased. The answer to this is the fact that in 1881 the percentage of deaths from all zymotic diseases was 26.67, and that the rate has gradually fallen to 16.47 in 1890; a diminution of nearly ten per cent. This certainly is a remarkable record, which cannot be explained by any of the so-called wave theories of disease and it proves, if it proves anything, the beneficial effect of sanitary regulations.

#### DISINFECTION.

The whole subject of disinfection has such an important bearing on the suppression of infectious diseases, that a few words regarding it may not be out of place at the present time. It is generally conceded that steam under pressure is the best disinfectant known. The arguments for and against sulphur dioxide, are so many and so convincing that one is left somewhat in doubt regarding this agent. Dr. L. H. Thoinot, an eminent hygienist of France, published a very interesting and instructive paper in the *Annales d'Hygiène Publique*, of October, 1890, on "Disinfection by Sulphur." After giving in detail the various arguments for and against the use of this substance he gave an account of a series of very carefully conducted experiments with the germs of septicaemia, malignant pustule, erysipelas, glanders, tubercle, typhoid fever, Asiatic cholera and diphtheria. He found that the germs of septicaemia, malignant pustule and erysipelas resisted absolutely the action of sulphurous acid, although it was used in large doses and with a prolonged exposure; while the microbes of glanders, tubercle, typhoid fever and diphtheria were absolutely destroyed. This observer in speaking of the use of sulphur as a disinfectant in variola says: "Former experiments, also, which have recently been criticised, teach us that sulphur is a good disinfectant for vaccine, and by analogy the conclusion has been reached that it is also an efficient disinfectant in variola. Its empirical use in epidemics of this disease has given satisfactory results. This writer recommends the use of sixty to seventy grams of sulphur to the cubic metre of space, a quantity somewhat larger than is generally used in this country, and twenty-four hours' exposure. Finally, this investigator gives as his opinion, based upon actual experiments, that disinfection by sulphurous acid should not be laid aside until we have a more perfect apparatus at our disposal, such as the stove for the generation of steam under pressure. In the meantime its scientific value should not be called in question, in certain cases; nor the signal service it can render in the time of an epidemic such as an epidemic of cholera where it can be easily and promptly instituted at slight expense, as a most efficient prophylactic agent.

Disinfection by a current of steam without pressure, which, until the year 1887, was used to such an extent on the Continent, is being gradually abandoned because of its unreliability and lack of penetrating power, and steam under pressure is being substituted.

There are many different forms of the disinfecting stove, but the principle is the same in each. This consists in having an iron receiver capable of standing a pressure of thirty pounds to the square inch and in which the temperature can be raised to 250° F., an iron truck on which to place the articles to be disinfected, a pipe for the admission of steam and one for the escape, a pressure gauge, and a thermometer. In the system of Rohrbach, there is a stage preliminary to that of disinfection which is said to increase the penetration, make the pressure uniform and causes even saturation. This is done by partially exhausting the air in the stove before admitting the steam. The time required for disinfection by steam under pressure is fifteen minutes for articles not specially contaminated. In the case of special infection an exposure of from thirty minutes to an hour is required.

The importance of a permanent disinfecting station in a large city cannot be overestimated. In Germany and also in France and in England, hygienic measures, of which this is a very important factor, receive a much more liberal support from the government than it is possible to obtain in this country. The disinfecting stations of Berlin, of Vienna and of Paris, are apt illustrations of this fact.

PLAN D.

The Disinfecting Station of Berlin.

Plan D<sup>4</sup> represents the public disinfecting station of Berlin, opened in the year 1886. This station occupies a lot of land about 126 feet deep, 149 feet wide at one end, and 137 at the other; a central building divides this plot into two nearly equal courts; one for the reception of articles to be disinfected; the other for the delivery of articles after disinfection; a narrow passage connects these two courts. In each court is a wagon-house about 16 feet by 32 for the reception of the disinfecting wagons. At one end of the central building is the boiler-house with two boilers; on one side of this is the coal-shed; on the other, bathrooms, water-closets and a place for the storage of chemicals. Immediately adjoining the boiler-house is the disinfecting apparatus, which consists of two rooms divided by a perfectly tight wall, and in which are the disinfecting stoves. Connected with the disinfecting chambers are two storage-rooms, each about 50 feet by 19; one for infected articles; the other for the disinfected. On

<sup>4</sup> Die Offentliche Gesundheits- und Krankenpflege der Stadt, Berlin, 1890, p. 98, et seq.

the dividing wall are racks for articles disinfected or to be disinfected. At the end and between these two storage-rooms is the administration chamber, which can be entered only from the courts, and in which are two tightly closed windows having an outlook on the storage-rooms. The disinfecting stoves, made by Schimmel & Co., are three double-walled, iron chests, each about eight feet high, five feet wide and nine feet long. Each stove has a manometer to indicate the degree of pressure. A, represents the court for infected articles; B, the storage-room; C, the wagon-shed; D, the water-closets and bathrooms; E, the boiler-house; F, the coal-shed; G, the court for disinfected articles; H, the disinfecting stoves; I, the storage-room for disinfected articles; K, the administration-room; L, the wagon-shed. The different parts of the station are connected by telephone. The utmost care is taken to prevent the contamination of disinfected articles either by the wagons or by the clothing of the disinfectors.

While the reliability of disinfection by steam cannot be disputed, it must be acknowledged that in certain conditions this process cannot be used, as, for example, in the disinfection of the walls of houses. For this purpose some gaseous disinfectant therefore is imperatively demanded. A painted wall can be disinfected by washing with a solution of corrosive sublimate, it is true, but for the cracked walls, covered with soiled paper, of the ordinary tenement-house, and for upholstered furniture, sulphurous acid seems to be the best agent to use; notwithstanding the fact that its disinfecting power has been disputed. Carefully conducted experiments prove, it is true, that when cultures of many microbes are placed on cloth and subjected to the fumes of sulphurous acid they are not sterilized; but the conditions are entirely different in the case of the microbes on the walls and floating in the air, for in the latter the germs are exposed directly to the action of the gas and are therefore more easily killed, while in the former, the fibre of the cloth protects them to a certain extent.

CHART F.

Percentage of Deaths from Croup, Diphtheria and Scarlatina to the Total Mortality in Berlin and Boston for Ten Years—  
Berlin .... 1881-90. Boston —

A study of Chart F, which shows the percentage of deaths from croup, diphtheria and scarlet fever to the total mortality for ten years 1881-90, indicates that in Boston, where sulphur is used, the rate has fallen from

9.28 to 4.95, a diminution of 4.33. In Berlin where the steam process is used, the rate has fallen from 8.63 to 5.66, a diminution of 2.97; 1.36 in favor of Boston. The municipal disinfecting station in Berlin, just described, was opened in 1886; for that year the rate was 4.38, and by following the broken line it will be seen that the percentage varied slightly during the subsequent years, but that in 1890, it reached 5.66, an increase of 1.28. In Boston, on the other hand, it will be seen by following the full line that in 1886 the rate was 5.44, and that in 1890, it was 4.95, a diminution of .49. It is of interest to note that the average percentage for ten years in Berlin is 6.76, and that in Boston it is 6.82. So far as the advantages to be gained from different methods of disinfection are concerned, the foregoing statistics show that the sulphur process, although it may be open to severe criticism, has been an important factor in causing a diminution in the number of cases of scarlet fever and diphtheria; and, on the other hand, that the steam process, although its scientific value cannot be denied, has not been such a potent agent for this purpose as might have been expected.

In conclusion, I would suggest the adoption of the following plan for the suppression of infectious diseases:

1. The prompt report of cases.
2. The removal to hospital of suitable cases, and the isolation of others.
3. The establishment of private hospitals, in which the patients can be under the care of their family physicians.
4. The posting of cards on houses where cases of disease exist.
5. The careful medical supervision of the public schools, not only for the purpose of detecting mild cases of disease; but also to prevent the return of children, who have been ill, until all danger of infection from them has passed.
6. The prohibition of public funerals.
7. The establishment of a disinfecting station and sanitary laundry.
8. The disinfection of the houses in which these diseases have occurred.
9. The establishment of a house of refuge for families during the disinfection of their homes.

In closing, let me add that I have no such Utopian ideas as to suppose, that even with the most elaborate system of disinfection; that with the most careful medical supervision of the schools; and that with the best arranged hospitals it will ever be possible to absolutely stamp out diphtheria and scarlet fever, but it is evident from the history of the course of these diseases, in Boston, during the past ten years, that a very considerable progress has been made towards their suppression.

AMATEUR ANATOMISTS. — Not long since, says a medical contemporary, an officer died at a certain British military station. At an afternoon "at home" of one of the leading ladies on the station, the captain's death was mentioned, and the hostess who "knew all about it," volunteered the information that he had died of disease of the kidneys, adding with someunction and a little bashfulness, "how thankful we women ought to be that we have no kidneys."

# RESECTION OF SECOND AND THIRD DIVISIONS OF FIFTH NERVE AT THE FORAMINA ROTUNDUM AND OVALE.<sup>1</sup>

BY S. J. MIXTER, M.D.

Visiting Surgeon, Carney Hospital; Surgeon to Out-Patients, Massachusetts General Hospital; Demonstrator of Anatomy, Harvard Medical School.

At a previous meeting of this Society, I reported three cases of resection of the third division of the fifth nerve at the foramen ovale. Since that time I have operated on two patients suffering from intense facial neuralgia, in both of whom the second as well as the third divisions being involved. I removed both nerves at their exit from the skull. I wish, in this paper, to call attention to the comparative ease with which both nerves may be reached through a single external incision, and also to speak of certain variations in the anatomy of the bony structures met with during the operation. Though these variations have been described by a few anatomists, I do not find them referred to by surgical writers; and without a knowledge of their existence, the operator might be greatly puzzled and hampered.

The method chosen for reaching the foramen ovale I have described elsewhere, and the incision through the origin of the temporal muscle and zygoma, given by Salzer,<sup>2</sup> is the one that seems to me the best, after five operations on the living, and a large number of experiments on the cadaver.

The first step in the operation, namely, turning down the flap with temporal muscle, zygoma and pterygoids, is simple enough, though the hemorrhage is always severe and only controlled by packing with sponges and compression with spatulae. When the external pterygoid plate is reached, and the soft parts are pushed back with the finger or blunt instruments, the anatomical variation alluded to may be encountered, as happened in one of my cases. As a general rule, there is a considerable space — enough to admit the end of the index finger — between the posterior border of the external pterygoid plate and the spinous process. In looking up the anatomy of the operation on various dry skulls, I was struck by the great difference in this space in different individuals, and in a skull which I brought from Paris I found that there was actually a bony bridge from the plate to the spinous process. This bridge is found, according to Civinini, Grüber, Henle and others, in a certain number of skulls, (Grüber says one in fourteen), and is simply a bridge of bone instead of the more usual ligament (ligamentum pterygospinosum) which occupies this position. Hyrtl describes also a bony bridge forming the "porus eotaphiteobuccinatorius," through which pass the motor divisions of the inferior maxillary nerve. The variations in bony and ligamentous structure, and their relations to the nerve and its branches, are fully described by Von Brunn,<sup>3</sup> and a minute description of them is unnecessary here. In a report on the "Progress of Anatomy," by Dr. Dwight, recently published in this JOURNAL,<sup>4</sup> there is an account of these variations. It is sufficient for the surgeon to know that such ligaments always, and bony bridges sometimes, occur in this region, and that in one-third of the cases the main divisions of the nerve are divided by such structures.

If, then, on reaching the external pterygoid plate the space between it and the spinous process is very small, or they are connected by a bony bridge, it is necessary to use either a chisel and cut through the obstruction, or to break it away with a blunt instrument until the finger passes easily to the foramen ovale, which is recognized by touch.

This bony bridge I have seen six times in about 125 skulls examined. Three of these were in dry skulls, two were in the cadaver, and one in the living patient. In one cadaver the bony bridge separated the divisions of the nerve trunk; (lingual, inside; inferior dental, etc., outside) and in the other, observed by Dr. Dwight, in a girl sixteen years of age, the nerve trunk was on the outside. In my patient, I was unable to decide definitely the relation, on account of the bleeding, but I think that the bridge separated the inferior dental and lingual branches.

Having a patient with a severe neuralgia in the second as well as third divisions of the nerve, I made several dissections on the cadaver with the idea of reaching also the foramen rotundum through the external opening previously described. I found that by separating the attachment of the external pterygoid muscle from the external plate until the pterygo-maxillary fissure was reached, the internal maxillary artery was exposed and easily tied, and then, in most cases, the nerve could be drawn out with a blunt hook of proper shape, seized with strong hemostatic forceps, and easily divided with a curved tenotome at the foramen rotundum. The whole contents of the sphenomaxillary fossa, is easily separated by a fine blunt instrument, and by means of the hemostatic forceps the branches of the nerve are twisted out; by this method a considerable portion of every branch of the nerve, also Meckel's ganglion and its connections, are removed.

In some cases a very marked projection at the anterior end of the pterygoid ridge (tuberculum spinosum — McAllister) prevents easy access to the sphenomaxillary fossa, and it is necessary to remove it with the chisel. This may be done without danger, as it represents only a thickening of the bone at this point, and not a deepening of the middle fossa of the skull.

After having performed the above operation, my attention was called to a very similar one, the nerves being reached through an incision under the zygoma. This method does not seem as anatomically correct as the one described, as there is greater danger of wounding the superior branches of the facial nerve, and the soft parts are divided at a point where their correct apposition after the operation is more difficult. The scar also is more prominent than in the temporal incision, of which all but a part of the anterior limb is covered by the hair. The temporal incision is not as direct perhaps, but it gives plenty of room for operating, and the nerve is as easily exposed as by the other operations.

The earlier methods of reaching the foramen ovale I have not described, as I see no reason why any one who has sufficient anatomical and surgical skill to do the operation, should divide the lower jaw at any point, when it can be reached without. The operation is a somewhat tedious one, as much of the hemorrhage has to be stopped by pressure, and sometimes the bleeding is very profuse.

The paralysis and contraction of the muscles of mastication, described as following excision of the third

<sup>1</sup> Reported at the meeting of the Boston Society for Medical Improvement, March 23, 1891.

<sup>2</sup> *Wien. med. Woch.*, 1887, xxxvii, 161.

<sup>3</sup> *Anat. Anzeiger*, 1891, vi, 967.

<sup>4</sup> *Vol. xxxv*, p. 575.

division, has caused little discomfort in the cases I have operated upon. The jaws should be opened widely every day after the first week, and wedges used by the patient, if necessary. The very slight stiffness is a small matter to the patient, when compared to his previous intense pain.

As regards the methods of reaching the foramen rotundum and Meckel's ganglion, by trephining the antrum, or resecting the upper jaw (osteoplastic), I can see no reason why they should be chosen in preference to the operation described, even though the neuralgia is limited to the second division. The removal of the nerve in the orbit certainly cannot reach the posterior dental branches, which so often seem to be the first ones affected by the disease.

An operation still more radical than resection of the nerve trunks at the base of the skull has been performed—resection of the Gasserian ganglion.<sup>6</sup> In none of my cases has the supraorbital branch been involved; and as there is apparently danger of ulceration of the cornea and loss of the eye from removal of the ganglion, I have considered it best not to undertake it.

The following cases were seen by Dr. J. J. Putnam, who advised resection of both the second and third divisions, as both were involved. These cases, added to those previously reported, make six in which I have resected the third division at the foramen ovale.

CASE I. Patient of Dr. Sylvester, Natick; man; age sixty-seven; severe facial neuralgia for five years. When first seen it was very severe, the most painful points being on the temple (auricula-temporal) and near the nose on the cheek (infraorbital). He was absolutely unable to work for three years.

The temporal incision was made, and on reaching the external pterygoid plate, the bony bridge (pterygo-spinosum) was found, which was broken through, together with a portion of the pterygoid plate. The nerve was divided at the foramen ovale, and the distal end twisted out. After tying the internal maxillary artery, the "tuberculum spinosum" was chiselled off, and the trunk of the superior maxillary nerve raised with a blunt hook. The contents of the speno-maxillary fossa were then freed from the bone, an opening being accidentally made into the posterior nares through which air bubbled as he breathed. The distal end of the nerve trunk was forcibly twisted out, as were any filaments remaining in the fossa.

The wound required no packing after the operation, and on the removal of the dressing, in a week, was found entirely healed. (Patient was shown at the meeting, four weeks after the operation. Now, three months after operation, there is no pain, and he is able to work.)

CASE II. Kindly referred to me for operation by Dr. Romans, at the Massachusetts General Hospital. Man; sixty-two; more or less pain for years, but very severe for a year. When first seen had most severe form of epileptiform neuralgia over the area supplied by the second and third divisions. This operation was much like the previous one, except that there was no "tuberculum spinosum" to be removed, the nasal cavity was not opened, and the foramen pterygo-spinosum was not present, though the pterygoid plate projected so far backward that its posterior edge had to be cut away. There was considerable hemorrhage, and iodoform gauze was packed in the

bottom of the wound. The gauze was removed in forty-eight hours. No suppuration. There was absolutely no pain from the time of operation until the patient's discharge from the hospital. I think that nothing more favorable can be said of so severe an operation than the statement of the patient, that he "would rather go through the operation any time than have the old pain for twenty-four hours."

CASE III.<sup>5</sup> German, male, age sixty-four. Severe epileptiform neuralgia of second division; slight neuralgia of third division. Referred to me for operation by Dr. C. J. Blake. Operation as in last two cases. Hemorrhage severe; wound, packed with iodoform gauze. Recovery rapid, and relief from pain immediate and complete. In this case there was some pain and roaring in ear on side operated upon, which on examination by Dr. Blake was found to be due to hemorrhage into membrana tympani. This symptom was present in one other case, and, as in this, was transient.

(August 10th. I have examined two of the above cases within a few days; and in both there is no pain. Case I is able to work regularly, which he has not done before for years.)

### OTALGIA.

BY CLARENCE J. BLAKE, M. D., BOSTON.

THE original use by earlier writers, (Itard and Bonafant, for instance) of the term *Otalgia*, as meaning pain in and about the ear, of either inflammatory or the less understood reflex origin, has, with the better definition of causes, gradually given place to more limited uses, until in its later definition and with the enlargement of our nomenclature, it means neuralgia of the ear itself, or "pain in the course and over the distribution of a nerve in the ear without fever."

In this sense neuralgia of the ear is, even with the broader definition of Roosa, an extremely rare disease, and is usually of general or immediate reflex origin, varies both as to time and degree in its manifestations, and is therefore frequently simulative, and can be differentiated from the pain due to a local inflammatory process often only by the most searching examination.

Of the neuralgias in and about the ear so completely defined by Dr. Green in his paper before the American Otological Society, 1874, the term *otalgia* would, most exclusively considered, include only neuralgia of the auricle, and external auditory canal, and of the middle ear, the correlative nerve supply of these parts being such as to afford ample opportunity for pain of purely reflex origin without reference to the possible causative trophic changes in the tissues of the ear itself, first adequately described by Dr. Green in the paper mentioned, and which should not be included here if we wish to keep to the more precise definition. This nerve supply includes, for the outer ear, nerves derived from the third cervical, the trigeminus and pneumogastric, and, for the middle ear, trigeminus, facial, glosso-pharyngeal, pneumogastric and great sympathetic, and in addition the tympanic plexus.

In the neuralgias both of the external and middle ear the pain may be divided into two classes, the persist-

<sup>1</sup> Read before the Boston Society for Medical Improvement, March 23, 1891.

<sup>2</sup> Operated upon after this paper was read.

<sup>6</sup> *Horn: Lancet*, 1896, II, 914.

ent and intermittent. The former class, in the external ear, includes the cases of hyperæsthesia usually associated with such disturbance of the general nervous system as may be found in neurasthenics, and as he has been seen in some instances associated with hysterical hemianæsthesia and provoked locally by temperature changes, especially by exposure to cold. This constant pain, exaggerated by the conditions last mentioned, is most commonly confined to the external auditory canal and the upper anterior portion of the concha, varies with the general conditions of the patient, increases with fatigue or other generally debilitating conditions, is relieved temporarily by protection of the parts, and disappears finally with the improvement in the general condition.

An illustrative case of this kind occurred in a slender woman, thirty years of age, the childless wife of a country clergyman of moderate means. She had no organic disease, had never been strong, however, was much given to home life and intellectual pursuits, and quickly paid the penalty in nervous over-tire and disturbance of digestion for any nervous over-strain entailing hurry or loss of sleep. Under these conditions she had coldness of the extremities (especially at night,) exaggerated knee-jerk, pain in the small of the back, insomniac tendency, and a continued pain referred principally to the region of the outer half of the external auditory canal and the bottom of the concha. This pain was more marked in her right ear than in her left, interfered with sleep unless soothed by applications of warmth, and sometimes disappeared only under the administration of an opiate. On the following day the pain would be less, but still constant, aggravated by exposure to a draught of air but not by light pressure, and, as before, relievable by protection. The ordinary means to this end were finally assisted in this case by painting the sensitive surface with a sixty-grain solution of nitrate of silver, the resultant coating seeming to have a sufficiently protective effect. The internal administration of quinine, both in the small and continuous and in the larger occasional dose, seemed to have no beneficial effect. The hearing in both ears was normal, there were no evidences of acute or hypertrophic inflammation and the neuralgia finally disappeared under general hygienic treatment, including rest, food, massage and tonics.

This case will serve to illustrate the otalgia continuous in character, of general reflex origin, the persistence of which soon begets apparently a hyperæsthesia of the adjoining parts, often so painful that the patient is unable to sleep on the affected side without an ear pillow, and sometimes, though rarely, associated with a hyperæsthesia acustica most marked for high tones.

The following case may be cited in illustration of the continued pain of determinable reflex origin:

A woman of forty five, of good habits and fair general health, but occasionally the subject of hemicrania after fatigue, was suddenly seized, late in the day, with pain gradually increasing in severity, continuous in character, referred to the depth of the left ear. An examination of the ear showed the external ear normal, without tenderness on pressure. The membrana tympani and middle ear to all appearances normal, and the hearing good. Examination of the jaw, however, showed a cavity left by the recent extraction of a lower bicuspid, which cavity was filled with the detritus of food and other material. The syringing out of this cavity, followed by the application of a few drops of a four-

per-cent. solution of cocaine, relieved the pain within a few minutes. It did not subsequently return.

The intermittent form of otalgia externa, is so far as I am aware, more common in the auricle and the posterior portion of the canal, rarely occurs independently of other neuralgic manifestations, and is, together with the neuralgia of the helix, more frequent in connection with the fugitive neuralgias of the occipito-parietal region than alone. The same may be said of the intermittent neuralgic pain of the middle ear, seldom felt in the middle ear only, generally conjoined with pain referred to the canal, so that it is sometimes difficult to get from the patient a correct definition of the most painful part.

The continuous pain of the middle ear, however distinctly reflex in its origin, the true otalgia media, is generally referred to the depth of the ear; occurs often independently of other neuralgic symptoms, though usually in a patient having neuralgic history; and finds its origin more frequently perhaps from the irritating cause of carious teeth than from any other form of the reflex suggestion, though this type of neuralgia has been observed in connection with diseases of, and after operations on, the nose, from irritation in the naso-pharynx at the mouth of the Eustachian tubes (J. Orne Green), and from exciting causes in the larynx (Langmaid).

Of the typical otalgia, certain points present themselves as important from the stand-point of differential diagnosis. The otalgia proper, for instance, rarely occurs in young children, frequently (comparatively speaking) in adults. A reflex cause which is apparently sufficient in a child to cause tissue changes evidences itself in the adult only in a pain which, if long continued may be, it is true, ultimately associated with tissue changes as well.

The intermittent otalgia is rarely found alone, but is almost always associated with other neuralgic symptoms, which help to differentiate the pain in the ear from a pain having a local inflammatory though concealed cause; it is, therefore, the continued otalgia which should especially call for that care in objective examination of the ear in addition to careful tests and attention to the general history demanded by all of these, cases from the practitioner who would avoid the mistake of cloaking with an anodyne a pain which is really evidence of a serious inflammatory process demanding surgical interference for its relief.

---

THE Albany Medical Annals collects the following from "The Annual Report on Laws Regulating Medical Practice," by Dr. R. J. Duglison. The answers were given to the questions of a State Board of Medical Examiners:

"Extra-uterine pregnancy may be a fungoid growth or tumor fibroid in its character, or any extra growth in the uterous would be called extra-uterine pregnancy.

"A breech presentation may be known by the sense of touch, the buttox being different in formation from the cranium. The anus is different from the mouth, absence of tongue and nose. Tiet your finger in the inguinal region soon as possible and assist your patient by firm but gentle tenton.

"The temperature of the system is variable. In health the enticle stands at 70 degrees."

## Medical Progress.

### RECENT PROGRESS IN FOOD, DRUGS AND ARTICLES OF DOMESTIC USE.

BY BENNETT F. DAVENPORT, M.D.

#### POLLUTION IN AIR OF LARGE MANUFACTURING CITY.<sup>1</sup>

A committee of the Naturalists' Society of Manchester has reported that they found snow carried to the ground large quantities of sulphuric and hydrochloric acids, and also some of the elements of sewage. They found the deposition upon vegetation was in direct proportion to the population, and the most injurious were due to the emanations from dwelling-houses. They estimated that in one day in Manchester two tons of "blacks" and three hundred-weight of sulphuric acid were deposited upon each square mile of the city area. The Royal Horticultural Society has appointed a committee to make similar investigations in London.

#### HEAT OF COMBUSTION OF THE COMMONER ILLUMINANTS, AND THE CONTAMINATION OF THE AIR CAUSED BY THEIR USE.<sup>2</sup>

The substances examined by the author consisted of candles (made of tallow, paraffin and stearin), petroleum oil, and gas. The tallow candles were moulded, the paraffin were the standard German candles, and the gas was from the public supply of Marburg, which is of the average quality. Both the petroleum and gas were burnt so as to produce a light of about one hundred candle power.

Substance.	Amount burnt.	CO <sub>2</sub> produced	Water vapor.	Heat units.
Gas: Siemen's regenerative lamp . . . . .	0.35 cb.m.	0.386 kilos.	0.394 kilos.	1843
Gas: Argand burner . . . . .	0.80 "	0.882 "	0.694 "	4113
Petroleum: Flat burner (3 hours). . . . .	0.60 kilos.	1.648 "	0.653 "	6220
Petroleum: Flat burner (3 hours). . . . .	"	1.876 "	0.762 "	"
Petroleum: Large round burner (3 hours). . . . .	0.20 "	0.549 "	0.218 "	2073
Petroleum: Large round burner (3 hours). . . . .	"	0.625 "	0.254 "	"
Paraffin . . . . .	0.77 "	2.298 "	0.911 "	7615
Stearin . . . . .	0.92 "	2.443 "	0.536 "	7881
Tallow . . . . .	1.00 "	2.581 "	0.941 "	8111

Upon burning one gramme of the several materials, the following results were obtained:

Substance.	Weight of Carbon.			Relative amounts.	
	By analysis	Waste gases as CO <sub>2</sub> .	Partially burnt.	As CO <sub>2</sub> .	Partially burnt.
Gas . . . . .	0.663	0.647	0.016	100	320
Tallow . . . . .	0.710	0.730	0.019	113	200
Stearin . . . . .	0.763	0.726	0.037	112	740
Paraffin . . . . .	0.830	0.821	0.018	127	360
Petroleum, 3 hrs. . . . .	0.858	0.751	0.107	116	2140
Petroleum, 8 to 13 hrs. . . . .	0.858	0.853	0.005	132	100

This, for a light of 100 candles, would become:

Siemen's burner . . . . .	0.39 cb. m. CO <sub>2</sub> .
Argand burner . . . . .	0.88 "
Petroleum, small and flat flame . . . . .	1.65 "
Petroleum, with large and round flame . . . . .	0.55 "
Candles . . . . .	2.5 to 2.7 "

The amount of hydrogen incompletely burnt was as follows:

Substance.	Weight of Hydrogen.			Relative amount partially burnt.
	By analysis	Waste gases as H <sub>2</sub> O.	Partially burnt.	
Tallow . . . . .	0.118	0.108	0.010	100
Stearin . . . . .	0.124	0.113	0.011	110
Paraffin . . . . .	0.152	0.135	0.017	170
Petroleum, 3 hrs. . . . .	0.138	0.121	0.017	170
Petroleum, 8 hrs. . . . .	0.138	0.141	0.003	—
Gas . . . . .	0.256	0.207	0.049	490

The products of the incomplete combustion of the hydrogen and carbon include carbonic oxide, nitrous and nitric, sulphurous and sulphuric acids. Experiments made with healthy guinea-pigs showed that they were able to breathe the air contaminated with the products of combustion of gas or candles, for days at a time, without permanent injury to their health; while men, the nose so quickly detecting the fumes, could not breathe air containing these substances in quantities far below the danger limit without great inconvenience.

#### COTTON GOODS CONTAINING ARSENIC.<sup>3</sup>

The British consul-general at Christiania reports that the imported textile goods, the sale of which had been prohibited in Norway during the year, on account of the presence of an excess of arsenic, consisted almost exclusively of British cotton prints. Of the samples examined, eleven per cent., against twenty-four per cent. in the year before, had exceeded the limit. The principal colors were blue and white, brown and white, black and white, and red with yellow.

In Norway there is thought to be special danger to children and persons in weak health from the use of textiles excessively colored with arsenical dyes, particularly from bed clothes.

#### ARSENIC IN COMMERCIAL ACIDS.<sup>4</sup>

Buchner reports that in 100 kilogrammes of English oil of vitriol and in muriatic acids he found 131 and 592 grammes of arsenious acid. As these acids are at the base of about all chemical products, the presence of traces of arsenic in such product is not very surprising.

#### VEGETABLE BUTTER.<sup>5</sup>

The manufacture of a vegetable butter from coconut oil has become a large business in France and Germany. The product obtained after Dr. Schlück's method is a perfectly white mass, of the consistency of butter, and of a sweet, neutral, agreeable flavor, melting at 25° C., and remarkably free from any tendency to turn rancid. It contains 99.63 per cent. of fatty matter.

Ordinary cows' milk butter contains about seven per cent. of butyric, caproic, capric, caprylic acids, etc. In margarine these soluble acids exist only in traces,

<sup>1</sup> Board of Trade Journal, January, 1891, p. 33.

<sup>2</sup> G. Buchner: Chem. Zeitung, 88, p. 43.

<sup>3</sup> P. Jeann: Mont. Scient., 1890, XXXI, 1116-19.

<sup>1</sup> Industries, x, 1891, p. 91.

<sup>2</sup> E. Cramer: Jour. f. Gasbeleuchtung, 34, pp. 27, 48, 65.

while this vegetable butter contains them in about the same amount as milk butter. It does not mix easily with milk butter, and such a mixture when saponified with an alcoholic solution of potash, and then made acid with sulphuric acid, will give out the very characteristic odor of cocaine ether. Even ten per cent. of it in such a mixture will yield the acid flavor and disagreeable taste of rancid coconut. The Reichert-Meissl-Wolff method of examination serves to detect fraudulent admixtures. As also it melts at some 10° C. below milk butter, its presence would be thus indicated.

#### CHINA TEAS.<sup>6</sup>

The author has undertaken to determine if there was any relation between the commercial prices of different teas and the amount of theine and tannin which they contained.

He reports a detailed table of his results and concludes that the prices do not depend upon the absolute amount of theine in the teas, but upon the relative percentage of theine to the total amount of tannin and products of fermentation. The greater this ratio the higher the price of the tea, and the more regular the fermentation the better the tea. He found the ratio of the theine to the other constituents ranged from 16 to 71 in the lower price teas, to 21.5 to 75.5 in the higher price and best teas.

#### THE CHEMISTRY OF WHISKEY AND ALLIED PRODUCTS.<sup>7</sup>

Brandy, an evident corruption of "Branntwein," that is, "burnt" or "distilled wine," is most properly applied to the spirit obtained by distillation from fermented grape sugar, either in the juice itself or that retained in the skin after their pressing. Of late years, however, it has become corrupted from its original and proper meaning, and has become so extended as to include spirit distilled from maize, rice and other cereals, and also from potatoes, turnips, beet roots, molasses, etc.

The *Berliner Börsen Zeitung* asks: "What do they understand by the word 'Cognac' in France?" and says: "The district of Charente is the place of origin of real 'Cognac,' and has, during the last seven years, produced an annual average of 20,000 hectolitres, while the annual export by France of liquor known as 'Cognac' has exceeded seven times this quantity. In trade, we usually understand by 'Cognac,' a brandy obtained by the distillation of wine, and which was formerly known as Franzbranntwein, that is, 'French brandy,' but it has been shown by analysts, and also in a bulky volume issued by the State Department of Hygiene, that there is no reliable means of distinguishing real brandy as distilled from wine from the spurious stuff. It will, nevertheless, be interesting to those in the trade to learn of a French court of law as to what it understands by the word 'Cognac.' A merchant who bought brandy in Valenciennes and labelled it 'Cognac,' was prosecuted for so doing, but was acquitted on the ground that the word 'Cognac' is not to be exclusively understood as descriptive of the place of production, but often, as in the present instance, a descriptive of the nature of the product. According to this decision, it is, then, to be regarded as sufficient when label announce the nature of goods to which they are affixed, and it is not requisite that

the contents of a bottle should have been produced in the place mentioned on the label. This fundamental decision is, however, not consistent with sentences pronounced by various French law courts upon manufacturers of sparkling wines, who have been heavily fined for introducing into trade wines which they described as 'champagne,' and which had undergone a similar process to that of the genuine article, but had not been made from wine grown in the champagne district."

It is well known that ethyl alcohol and carbonic acid are by no means the sole products of fermentation by yeast. Succinic acid and glycerine are constant products, and also the higher homologues of ethyl alcohol in small but distinct amounts. The species of ferment, acting, changes the result. Thus, ordinary brewer's yeast, *saccharomyces cerevisia*, produces subsidiary products distinctly different from those of the ferment of grape skins, *saccharomyces ellipsoides*. In fact it has been found that by adding the latter ferment to molasses and other saccharine liquids distinct from grape-juice, the products of the fermentation after distillation has all the character of Cognac brandy.

Many attempts have been made to estimate the fusel oil in spirits, but accuracy has been found to be by no means easy to attain. It was probably in great measure the result of omitting certain important precautions which led Sir James Bell, the chief chemist of the Inland Revenue Department, to assert, before a committee of the House of Commons, upon British and Foreign Spirits, that the proportion of amyl alcohol was somewhat greater in matured spirits than in new. This anomalous conclusion is so opposed to chemical expectation and common experience that it is important to know that the methods of analysis upon which it was based are open to exception.

The exact cause of the improvement in spirits by maturing in casks, is by no means clearly made out. It is usually ascribed to oxidation and the formation of ethers, which certainly does occur, but it is doubtful if the improvement in flavor is due as much to this cause as to the change in more undefined constituents. One thing seems to be quite certain, and that is, that the proportion of amyl alcohol, and even fusel oil in the widest sense, present in whiskey, either new or old, is very trifling, and it is difficult to understand that it is capable of producing the injurious physiological effect attributed to it.

With a view of ascertaining whether it did me any harm, I have, for some time past, been taking every evening when at home, some whiskey to which two per cent. of fusel oil had been added, and yet I have not had even a headache from it. My friends say that it is because I have not taken enough of it. It is extremely nauseous, but it leaves no doubt in my mind that the effects of amyl alcohol, or whatever other substances there may be in fusel oil, have been absurdly exaggerated. I believe the whole theory was trumped up by some alchemist about the year 1, and yet people have gone on making these statements while there was not a single figure or accurately observed fact to support them.

I have no doubt the amyl alcohol and other subsidiary constituents of spirituous liquids are of great importance with respect to the flavor and bouquet, but I have grave doubts of their physiological importance. It is worth remembering that taking the whole oxidizable substances present in whiskey and calling them amyl alcohol, there is not more than one-tenth of one

<sup>6</sup> *Proc. Roy. Soc. Chem. Soc.*, vol. p. 558.

<sup>7</sup> *A. H. Allen, Jour. Soc. Chem. Industry*, 1891, p. 303.

per cent., or say a drop in a wine glass, and hence any local effects, such as have been attributed to fusel oil, are more probably due to the ordinary ethyl alcohol than the minute quantity of amyl alcohol contained in it, whatever may be the case as to the effect on the system.

In the discussion which followed the reading of the paper, J. A. Wanklyn said that, for fifteen or twenty years he had been of the opinion that amyl alcohol had nothing to do with the injurious effects of whiskey. He had long thought such effects were due to some exceedingly powerful essential oils. W. C. Samuel reported that he had also personally experimented for a month with a spirit to which various percentages of fusel oil had been added, and had found no ill effect to result, except the nauseousness. Dr. W. S. Squire said that in the manufacture of whiskey there was practically no attempt at purification. It was certain that the spirit improved if stored in wood but not if in glass. He thought the aldehyde probably the only constituent which would oxidize, and from its great volatility would be the first body to escape by evaporation. The fusel oil he did not think diminished in the process of maturing, but the other more volatile bodies disappeared to a large extent. One cause of the improvement by ageing was the practice of storing whiskey in sherry casks. If, however, this cask had already been once used for this purpose, the second lot of whiskey would not improve in the same degree as the first had, while if new casks were used the improvement was still less. He felt no doubt that if the more volatile products which came from the top of the still were not returned into the distillation, the maturing of the spirit would take much less time than at present. Yet distillers were extremely conservative, and objected to all change. In a large Dublin distillery where a man was killed by the breaking of a rope used in hoisting up the grain, the distiller had objected to the use of a chain, as recommended by the jury, on the ground that any change in the method of working would spoil his whiskey. Mr. F. H. P. Coats reported that it had been shown that if grape skins were sterilized so as to destroy the common organisms, and then were inoculated with a growth from the grape used for the manufacture of special highly-flavored wines, the effect was that the bouquet and flavor of the common wine were indistinguishable from those of the high-priced wines made from the special grapes. It would, therefore, appear that less importance attached to the material from which the beverage was made, than to the cultivation of those special ferments which would impart to it any flavor which might be desired.

#### ACIDITY OF MILK.<sup>8</sup>

After determining the acidity of four to five hundred samples of milk, he reports that as delivered to the London trade it has an average acidity equal to .20 per cent. of lactic acid; that this will usually develop within eight hours of the milking. In England, within thirty to forty hours later, the acidity will rise to .35 or .40 per cent., at which point it acquires an acid taste, and is said to be sour.

Usually at an acidity of .60 to .70 per cent. it curdles. Even if kept for a long period it rarely developed a greater quantity of lactic acid than two per cent. The highest acidity found after 117 days of keeping was 2.34 per cent. The reason of this is,

<sup>8</sup> A. W. Stokes: *The Analyst*, 1891, p. 122.

that when this amount of acidity is reached the acid found is destructive to the fungus forming it. Milk, which has not yet developed an acidity of quite .30 per cent., will yet coagulate on boiling. This is, therefore, the customary method of the trade for testing the freshness of a milk. Milk which had been boiled kept sweet twenty hours longer than the unboiled. Boiling was as efficacious as the use of one part per one thousand of any of the preservatives used in the milk trade. Of these he found boric acid was the best, two parts of which to the one thousand of milk would keep it fresh for forty-two hours longer. Whatever was used, he found that it had an acid taste on reaching an acidity of .50 per cent.

#### COAL-TAR COLORS.<sup>9</sup>

In foods and articles of domestic use the following yellow colors have been found to be perfectly harmless, or very nearly so, when pure: Naphthol-yellow S, Fast-yellow R, Brilliant-yellow, Orange I, Bismarck-brown, Sudan I, Ponceau 4, G. B., Chrysoidin, Diphenylamin-orange, Azarin, Fast-brown, Chrysamin R, and Dimethylamidoazobenzol or Butter-yellow.

The following yellows were found to be poisonous: Picric acid, Safron-surrogate or Victoria-yellow, Mar-tius-yellow, Aurantia or Imperial-yellow, Orange II, Metalin-yellow, and Safranin.

The following reds were harmless, or very nearly so: Soluble-rouge or Azobin, Soluble-purple or Neucoccin, Bordeaux B, Ponceau R, Metanitraozotin, Aunatto-substitute or Naphthion-red, Congo-red, Fuchsin, Acid fuchsin, Corallin or Rosolic acid, and Eosin. None of those yet known have proved poisonous.

The following greens are all harmless: Dinitroso-resorcin, also Naphthol, Acid or Helvetia, and Malachite-greens.

The following blues, violets and blacks are also harmless: Water or China-blue, Indulin, Indophenol, Coernlin and Alizarin and Methylene-blues, Methyl and Acid Violets, Wool and Naphthol-blacks.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, Monday, March 23, 1891, the President, DR. FREDERICK I. KNIGHT, in the chair.

#### ANATOMICAL SPECIMENS.

DR. HOMANS showed a specimen of cysto-sarcoma of the testicle, on which Dr. W. F. Whitney reported as follows: "The testicle was symmetrically enlarged to about three times the normal size. The section surface showed numerous small, irregular cysts filled with a thin yellowish fluid. Between these there was a soft grayish tissue, which on microscopic examination was found to be made up of large round cells with little intercellular substance."

Dr. Homans also showed the specimen of an amputation at the lower third of the leg. The pathological examination made by Dr. Whitney gave the following result:

"The foot and lower part of the leg showed an old

<sup>9</sup> Lehmann's *Praktische Hygiene*, 1890, p. 545.

fracture into the lower end of the tibia, with large fragment lying loosely attached as a sequestrum. The tissues about the joint were thickened, and traversed in various directions by sinuses."

Dr. Homans also showed a specimen of spindle-celled sarcoma of the abdomen removed from a woman thirty-five years of age. The operation was undertaken because the tumor was cystic and more or less connected with one ovary. On opening the abdomen the omentum was seen filled with large vessels of a dark color, and covering the growth to which it was adherent. When this omentum was more or less separated, hemorrhage was quite free. Upon careful examination a sarcoma attached to the intestines and broad ligament, and pretty well filling the lower part of the abdominal cavity, was found. Having started to remove the growth, it was necessary to finish, as the hemorrhage was very free. A part of the tumor was cystic, and contained considerable fluid. Dr. Whitney reports that it is a spindle-celled sarcoma.

Dr. A. T. CABOT showed the specimen from a case of ruptured tubal pregnancy.

The patient was a young woman of twenty-eight, who had been married for several years. She had never been pregnant, but her menses had always come irregularly, so that when on the 10th of December, 1890, she passed her menstrual period, and had but a slight show a week later, nothing especial was thought of it. About the 5th of January, 1891, she was suddenly seized with a sharp pain in the lower part of the abdomen. She was examined four days later by Dr. C. S. Millet, who was called to see her, and he found then a hard resistant mass in the lower right segment of the abdomen. She had had in the mean time one or two attacks of sharp pain, requiring considerable doses of morphia to give her even comparative comfort.

Her temperature gradually rose, and on the 12th of January, she then being in a high fever with a pulse at 126, and a temperature of 102°, Dr. Cabot saw her in consultation with Dr. Millet. It being plain that something was going on in the abdomen which called for a laparotomy, no vaginal examination was made in order that the fingers might be kept clean for the laparotomy.

The patient was etherized, and an incision made along the right line a semi-lunaris. At once upon opening the peritoneum there was a gush of dark red blood. The opening was enlarged, and the resistant mass found to consist mainly of clots of blood, which were turned out. A small mass attached to the right side of the uterus was now felt; and the true nature of the case being now clear, this was ligated and removed. The peritoneal toilet was made as rapidly as possible, the abdominal cavity being thoroughly irrigated with warm water. A glass drainage-tube was inserted to the bottom of the pelvis, and the wound was closed.

The patient made a rather slow, but uninterrupted recovery, and now is about the house. The portion removed was a Fallopian tube, which showed a considerable dilatation near its fimbriated extremity. This dilated portion had a smooth lining, and was partly filled by a rather firm clot. Its wall was ruptured on one side. No fetus could be found. Dr. C. S. Millet examined the specimen in the fresh state, and felt no doubt that the dilated portion of the Fallopian tube was lined by an ovum.

Dr. J. J. PERSAM read a paper on

# PERSONAL OBSERVATIONS ON THE PATHOLOGY AND TREATMENT OF NEURALGIA OF THE FIFTH PAIR, ILLUSTRATED WITH PATHOLOGICAL SPECIMENS.<sup>1</sup>

DR. S. J. MIXTER described the

## RESECTION OF SECOND AND THIRD DIVISIONS OF FIFTH NERVE AT THE FORAMINA ROTUNDEUM AND OVALE.<sup>2</sup>

Dr. CABOT said that he had done a number of operations on the various branches of the fifth pair of nerves, with more or less success. When the operation was done upon the peripheral branches, he thought it important to always remove all of that portion of the nerve which lay within the bony canal. When the inferior dental was the nerve involved, he operated by trephining opposite the dental foramen, cutting the nerve at that point, then seeking it at its emergence from the mental foramen, seizing that end of the nerve, and pulling the trunk out of the whole length of the canal in the bone. He had operated in this way on all three branches, the supraorbital, the infraorbital and the inferior dental nerve at the same time with good results.

He reported a case in which two years ago he operated upon the inferior dental nerve, in the manner described, for severe, long-standing neuralgia about the corner of the mouth and chin. The relief following this operation was entire and lasted for about twenty months, at the end of which time the neuralgia returned. It being thought at that time by Dr. Walton, who saw the case in consultation, as well as by himself, that the return of pain might be due to the regeneration or survival of some fibres of the nerve in the canal, the wounds were re-opened, and all of the soft parts that could be reached within the canal were drawn out and cut off. A hot probe was also passed into the dental foramen to destroy any nerves that remained. This operation did not afford relief, so that later he cut down after the manner recommended by Zuckerkandl, and removed a portion of the nerve at its emergence from the foramen ovale. This was done three or four months ago, and is thus far a perfect success.

Dr. J. C. WARREN: I am under the impression that an operation like that which Dr. Mixter has described was originally proposed by Dr. Pancoast of Philadelphia. I am not sure whether he performed the operation or not. I think he was one of the first to divide the nerve at the foramen ovale.

In regard to the division of the infraorbital nerve, it is a very simple operation, I think. The patient receives very little shock or disturbance and recovers very readily; and it certainly promises, in the great majority of cases, very satisfactory results. Many surgeons are in the habit of trephining the antrum to divide this nerve. It seems to me that this is unnecessary. The operation which contemplated following the nerve up through the division in the orbit promised sufficiently satisfactory results by following that method rather than the one that contemplated going through the antrum and seeking the origin of the nerve by the opening of the farther wall.

In one case which I had the operation had to be repeated, and at the second operation there was found a distinct renewal of the nerve fibre. Since the last operation, there has been no pain as far as I am aware. That operation was performed two years ago.

<sup>1</sup> See page 157 of the Journal.

<sup>2</sup> See page 161 of the Journal.

DR. D. W. CHEEVER: The experience that I have had is of cases seen some time ago. I have the records and results of five operations,—one for the infraorbital, one inferior dental, one at the foramen rotundum with Meckel's ganglion, and two of the foramen ovale. One was much relieved; one was not relieved; two were apparently cured so far as heard from; one was operated on twice, and finally relieved. There is an interesting history to one of the cases that I will read later.

With regard to the operation, the one formerly done was known as Carnochan's operation; first done I think, by him in New York. That consisted in trephining the antrum, following the nerve up under the orbit, cutting through the posterior wall of the antrum, and removing the nerve and Meckel's ganglion at the foramen. The other operation at the foramen ovale is, I think, to be justly attributed to Dr. Pancoast, and consisted in reaching the foramen ovale by cutting the coronoid process of the lower jaw, and not by cutting the zygoma. The operation by cutting the jaw is the one I have always done, and I have no experience with the other.

In 1873 I operated on a woman of sixty-five who had had the tic douloureux eighteen years in the left cheek and side of the nose. The operation was done by trephining the antrum, and the wound closed, and the patient was discharged in about two weeks. At first the pain was quiet, it slowly recurred, but did not resume its paroxysmal character. Before the patient left the hospital, however, she required opium, showing that the result of the operation was incomplete. Subsequently, according to Trousseau's plan, she was narcotized, taking many grains a day. Afterwards this was discontinued, and she got into a pretty comfortable state of health.

Two years after the operation, in reply to a letter of inquiry whether she was benefited, she said "Only to destroy the pain in the immediate locality of the operation. On the other cheek, temple and both lower jaws it is just as bad as ever." This species of neuralgia was described by Trousseau as of the epileptiform variety. An attack would be brought on by opening the door, for instance, or any slight noise. Trousseau says this is the most intractable of all; and in this the operation failed, and his method of narcotization also failed.

The same year Dr. Thorndike operated on a man sixty-one years of age, and so far as heard from, that case was cured, and there was no recurrence of the pain. He remained in the hospital some weeks, and never required any opium.

The most interesting case, however, is this: "Facial neuralgia of the inferior dental nerve; three operations to excise and remove, etc." The first step she took to relieve the pain was to have the teeth drawn. The first operation was to trephine the lower jaw. The nerve was cut out the full width of the hole, and the patient slept at first. After a week she had no spasms in the jaw; but in about ten days the paroxysms came back as severely as before the operation. A second operation was done a few months afterwards. She came back to the hospital, and wished it. At this time it appeared to me probable that some filaments of the nerve had got caught in the jaw, and that the operation had not been thorough enough. The trephine hole was again uncovered, the dental canal opened, and the nerve destroyed for some distance up and

down. Finally, the stump of the nerve was cut off from its entrance into the inferior dental canal. This was the second operation. This time she had no spasms for two weeks, and was considerably relieved. For seven weeks she did well; then the pain returned in the same cheek; and a third operation was done in about two months afterwards. At this time what is known as Pancoast's operation was done. Dr. Gannett failed to find evidence of degeneration in the nerve removed. The patient slowly healed up.

Apparently she was relieved only of the paroxysmal pain and not cured.

DR. WEBBER: I have been very much interested in the paper and all that has been said. I think Dr. Putnam deserves a great deal of credit for working up the pathology of those nerves so carefully. I think this is very instructive, and will show us the reason for advising an operation comparatively early and not putting it off. It must be that these degenerative, inflammatory changes progressing will involve larger stretches of the nerve, involve other branches; and it is important, as it seems to me, to operate in season. These neuralgias are the most trying of affections to the patient and physician.

DR. WALTON: I have advised and seen quite a number of these deep operations, and have been very much interested in Dr. Putnam's exposition. The possibilities in this branch of surgery should be widely known. Dr. Putnam has very wisely made prominent the division of neuralgias into these two classes, the ordinary recurrent form (largely and generally reflex), and a second class which includes those characterized by persistent epileptiform seizures of great violence and lasting many years, especially common in middle-aged and elderly persons. This second class one learns to recognize almost at a glance, and I quite agree with Dr. Putnam that it is of little use in these cases to begin with the ordinary routine treatment before resorting to operation. It is almost cruel to make these patients undergo this terrible pain year after year while we try these other methods, if we are sure we have such a case in hand. The histological results seem to justify this view, as almost without exception these nerves are found to be diseased.

In regard to the question of operating high up. The principal reason why the fifth nerve is so liable to neuralgia, aside from reflex causes and its dental distribution, is that it runs through bony canals and over bony prominences. This tends to set up inflammation and disease in the nerve, and consequently where we have one of these cases in hand, it seems futile to operate at the point of emergence, and we will sooner or later have to have recourse to the higher operation. In Dr. Cabot's case, where the first operation relieved temporarily, I dare say that a satisfactory explanation was that there was diseased nerve higher up than the first operation, and that the pain was referred to the point of emergence through the irritation of those fibres affected. The third operation at the foramen ovale, before the nerve had entered upon its course through the bone, removed the difficulty entirely and removed it for good.

I have an illustration in a case (not connected with the fifth nerve) which shows the futility of other applications for a pain resulting from organic trouble affecting the nerve. This was the case of a professor of astronomy in a Wisconsin college, who consulted me in regard to a pain in his index finger in the course

of one of the nerve branches. This pain he had had two years, and it was getting more and more severe and spreading up the arm. He had a sensitive scar over the point where the pain started, which had been there fourteen years, since he cut the finger with a chisel. That the cut had injured the nerve was shown by the complete numbness in the region supplied by this branch. I advised trying other treatment for a time, and in case of non-success resorting to operation. I applied electricity, gave strychnia and other tonics, but nothing seemed to benefit him except slightly, and in the course of about three weeks I advised operation. Dr. Richardson did the operation, and found a neuroma in the course of the nerve, which was excised. About a half-inch of the nerve was removed. An interesting feature of the case was that the sensation, which had been lost for fourteen years, reappeared. The area of sensibility gradually lessened until finally he could feel as well in that part of the finger as in any other. The case shows also how much a nerve will stand, and how it may become regenerated if operative means are resorted to.

I was very glad to hear of Dr. Mixer's operation upon the case where he operated for the second and third branches. The result of the operation has been very satisfactory. It seems very ingenious in him to have combined the two operations. I see no reason why it should not be done. I should agree with Dr. Cheever that the lateral operation is the preferable way to reach the sphenopalatine ganglion.

It is important to bear in mind the distribution of the buccal branch of the third division. I have known a case of neuralgia of the third branch to be mistaken for that of the second, through lack of familiarity of this distribution. The pain was around the angle of the mouth, the region supplied by the buccal branch which is sent off too high up to be reached by the ordinary operations. This distribution led me to advise operation at the foramen ovale, which was done with perfect success, I believe, by Dr. Richardson.

With regard to the question of reflex neuralgia, and what is practically a neuralgia of the meninges, namely, migraine, I should probably lay more stress than Dr. Putnam on reflex causes. I think the majority of ordinary facial neuralgias come from reflex causes, and especially the teeth. We are too much influenced by these cases of neuralgia in which tooth aching has been pulled out without relief. Such cases should not cause us to underrate the part played by dental irritation. I think those cases are really exceptional as regards ordinary neuralgias. I have seen many cases where there was absolutely no question of its coming from the teeth. I remember a case of very violent neuralgia in a patient whose teeth were all beautifully filled, nor did the pain even start, as it generally does, from any particular tooth; it had, however, started after the filling of a certain tooth. There was no tenderness on percussion. The dentist finally removed the filling at my request, with instant relief of pain, and himself said the tooth had been improperly excavated. I have had occasion of late to see a number of cases of neuralgia starting from dental irritation of various sorts. The crowding of a wisdom tooth, for example, is liable to produce a pain in the temporal region. It is well to be familiar with the directions in which the reflex neuralgias will be referred.

With regard to migraine, I think the majority of cases come from reflex causes, more especially errors of re-

fraction, though I am not sufficiently enthusiastic to say they all come from this source. I have seen the accidental inversion of a cylindrical glass with oblique axis, cause daily migraine, which only disappeared after rectifying the mistake.

As I understand him, Dr. Putnam's idea is that in these cases where there is a reflex cause for neuralgia, it may be that there is a peculiar idiosyncrasy or irritability of the nerve centres, which renders them more ready to react to a reflex cause than a healthy nerve centre. I have no doubt this condition obtains in certain cases; but if it is so in the majority, I do not understand why the neuralgia disappears when we remove the exciting cause.

One reason why the fifth nerve is so liable to neuralgia (besides its peculiar course) is that this is the one nerve that practically comes to the surface, which it does in the carious tooth, where it is exposed not only to mechanical but to deleterious chemical influences, a fact which should be borne in mind in investigating all cases of acute trigeminal neuralgia.

DR. MORTON PRINCE: I think Dr. Putnam's paper is a very valuable contribution to our knowledge of this subject. He has suggested many points of practical importance in pathology and treatment. It was not so many years ago that we looked upon neuralgias in general as a purely functional disease, and it is only within the last few years that the fact has been forced upon us that many, if not most, of the severer neuralgias are due to neuritis. But for practical purposes, I think we must distinguish between the acute or subacute cases and the more intractable chronic cases. It is amongst the acute or subacute cases that, in my experience at least, we find those of a reflex nature. We can study this very prettily at times in persons whose vitality is at a low ebb, as in cases of neurasthenia. In such cases it is possible at times to watch the diffusion of an external irritation from one centre to another, setting up one neuralgia after another. On the other hand, I, myself, have not been able to trace the reflex process so distinctly, as Dr. Walton has, in the more chronic cases.

The acute and subacute cases yield quite readily to other forms of treatment. There are on record many subacute and chronic cases which have yielded to electricity in the form of faradism applied with the brush. I have not had experience with this method myself. The more chronic cases, I think, as a rule, must eventually come to operation, as Dr. Putnam suggests; but it must also be borne in mind that they also sometimes yield to other forms of treatment. The very worst case I have ever seen was cured by galvanism. It was a case resembling very much such a case as Dr. Cheever has described to night. It was of the epileptiform variety. The spasms were brought on by the slightest provocation, and the man was a perfect wreck physically and morally, and yet his disease yielded rapidly to treatment by galvanism. There was immediate improvement, and now at the end of a year he still continues in perfect health. In his case the neuralgia was unquestionably due to a neuritis, as there was a decided anesthesia over the whole cheek supplied by the affected nerve. The case is also of interest as illustrating another point which Dr. Putnam has brought out, and that is, that an external irritation may be the immediate cause of a neuralgia, but it is not for all that the primary cause. This same man had had a previous attack a year or more before, and

a medical gentleman found a plug of wax in his ear; after removing it the neuralgia ceased, and the case was reported in the *Boston Medical and Surgical Journal* as a case of reflex neuralgia cured by the removal of a piece of wax from the ear. The neuralgia afterwards came back, and the case drifted into my hands. There was unquestionably inflammation of the nerve, and the plug of wax only served as an exciting cause to bring on an attack. It seems to me very difficult to prove whether an external irritation, such as this patient felt, is merely the exciting cause or the primary cause. I do not think I ever ordered the teeth out. They always came to me after they were pulled out. The neuralgia in such cases had not been diminished. It may be that the inflammation in such cases has spread farther along the course of the nerve, but it is a very hard thing to prove; nor have I had very much luck in the cure of migraine by correcting errors of refraction. To speak frankly, I have become very tired of having the eyes of these patients fitted to glasses. I know a good many cases have been cured, but perhaps I have had rather hard luck at it. Such cases as have come under my care have not been very much benefited.

DR. P. C. KNAPP: I can say almost nothing from my own observation in regard to the surgical treatment or in regard to the pathological changes in the fifth nerve. I think we are all of us indebted to Dr. Putnam for his very careful study. I have, however, never yet seen a case of facial neuralgia where I have advised operation. Doubtless there are various cases of facial neuralgia which have come to me at the hospital where, if they continued under my care, I should have advised an operation. They come once or so, and disappear; so that I can speak only of the medical treatment. I agree fully with Dr. Putnam in his praise of aconitine. There is another form of treatment, not spoken of, from which I have recently had rather startling success, and that is in the use of anti-syphilitic remedies where there was no probability of syphilis. I had, some two months ago, a lady come to me from the northern part of Vermont with a history of most intense epileptiform neuralgia, beginning some four or five years before, where, upon the most careful inquiry, I could get no evidence whatever of syphilis. She had been to another neurologist in the city who had told her the only thing to be done was to have an operation, to which she was very averse. The attacks had had intervals of remission in the past, but from the first of September until January, when I saw her, she was having most frightful twinges of neuralgia many times each day. Any slight draught, an attempt to eat, any jar, would bring on the pain. I gave her aconitine and antisyphilitic treatment, and for two months she has been entirely free from her neuralgia. It is too soon to speak of a cure, of course. I supposed from the probabilities that it was one where operation would be necessary.

I agree fully with Dr. Prince in regard to the reflex neuralgias and the reflex neuroses in general. The more cases that I see, the more carefully I go into the symptoms, the more thoroughly and deeply I hunt for reflex causes, the more pains I take to get these reflex causes removed, the fewer cures I find from such treatment alone. The cases of neuralgia of the lower jaw of long standing that I see, have usually had the teeth out. Of course, I occasionally see a case that comes reporting pain in the face for two or

three days; I find a bad tooth there, and tell them to go to the dentist and have that tooth seen to, and if they have further trouble to come back.

In case of migraine, I grow more and more sceptical of the cases which are immediately and permanently cured by the removal of a plug of wax from the external auditory canal or the removal of a carious tooth or the removal of some remote irritant. There have been in the history of neurology a good many beautiful reflex theories, reflex paraplegias from a long prepuce, the various reflex nervous conditions arising from the ovaries, and the ascription of all forms of nervous disease, organic and functional, to the ocular muscles.

DR. CLARENCE J. BLAKE read a paper on

#### OTALGIA.\*

DR. JACK: I think the important part played by the teeth in otalgia has been pretty well touched upon. It is a frequent occurrence at the infirmary to have children come in suffering with pain in the ear, in whom no acute inflammation of the ear is found. The teeth are then inspected, and if any are found unsound the case is referred to the dentist, with instructions to return if the pain does not cease afterwards. I remember several cases of otalgia in adults entirely relieved by treatment directed wholly to the nose. I should also like to emphasize what Dr. Blake has put rather strongly in his paper, on the importance of determining whether a patient suffering from pain in or about the ear has an otalgia or a commencing acute inflammation of the middle-ear. Cases not infrequently occur in which beginning serious inflammation has received treatment for neuralgia and valuable time been lost.

DR. PUTNAM: I would like to put myself on record in regard to the reflex influences. What I meant to indicate was that migraine is a special disease and has its own characteristics, and that to a great extent it may be said that the other forms of facial neuralgias and other neuralgias of the body are special diseases with their characteristics, and that although these diseases may from time to time be provoked by some reflex cause, they are not simply the expression of activity of that cause. Furthermore, I do strongly believe that in the case of a disease so distinctly hereditary and constitutional as migraine, it is highly improbable that the reflex causes should be nearly so prominent as in the case of facial neuralgia.

I think Dr. Starr handled this subject with great judgment a year ago, when the matter of ocular reflexes and gynecological reflexes were in debate. He pointed out that the reaction of a nerve centre to any irritating cause depends largely on the degree of irritability of the nerve centre. As neurologists we have to admit that in the great majority of cases the main condition at fault is the condition of the nerve centres, and that neurasthenia and migraine are to be treated on that basis.

DR. CREEVER: I should like to correct Dr. Walton if he thought I said the way to reach the foramen rotundum was by the method described by Dr. Mixer, and not by trephining. I do not know but that Dr. Mixer's method is the better way. That remark, however, should be credited to him, mine being confined to the old operation.

\* See page 165 of the Journal.

## Recent Literature.

*Institut de Chirurgie. Annl.*, 1890-91. Bucuresci : Lito-lipografia Carol Göbl.

Under this title, Professor Assaky, of Bukharest, dedicates to the students of medicine a first volume of clinical instruction, based upon original investigation made in connection with two practical courses : surgical anatomy and special operations.

Part I of this book (two hundred pages) contains results of researches, by ten physicians, concerning rheumatism, pulse and temperature, therapeutic action of di-iodo-salicylic acid, abdominal tumors, and cranio-cerebral topography, *et al.*

These reports are in detail, so that one can follow the cases with exactitude. The article on cerebral localization, by Dr. Assaky, is especially valuable because of the plates, which are numerous and elaborately elucidated by color, lines and figures. His reports of abdominal operations are accompanied by a number of photo-engravings.

In Part II (one hundred pages) are found some of Professor Assaky's clinical lectures : (1) Descriptions of operations in various diseases in connection with the uterus and its physiological annexes ; (2) the tabulated histories of several cases of tuberculosis treated with Koch's lymph.

The material portion of this work is excellent, most creditable to the paper-maker, the printer and the binder.

Professor Assaky is also editor-in-chief of the Roumanian medical periodical, *Clinica*, a recently established journal published in Bukharest. An extended notice of it was given in this JOURNAL some time ago.

Later issues have furnished valuable additions to "the healing art," in clinical reports and contributions to hygiene — looking toward rational, preventive sanitation.

F. B. S.

*Oeuvres Complètes de J. M. CHARCOT. Tome IX : Hémorrhagie et Ramollissement du Cerveau ; Métallothérapie et Hypnotisme ; Electrothérapie. 8vo, pp. viii, 571. With 34 illustrations in the text and 13 plates. Paris : Aux Bureaux du Progrès Médical. 1890.*

This, the ninth volume in the series of Charcot's collected works now in progress of publication, is not, like the preceding volumes on nervous diseases, made up from the lectures reported by his pupils, but is merely a collection of various articles which have appeared in medical journals for the past twenty-five years, many of which are, of course, familiar. Thus in the section on cerebral hemorrhage we find the familiar account of the influence of military aneurisms in the production of hemorrhage, originally published many years ago ; as well as numerous brief notes of comparatively little importance. The work itself, therefore, brings us nothing new. It is of value, however, in collecting various articles which would otherwise have to be sought in old files of journals. A part of them were substantial contributions to our knowledge, while others would never have been reprinted except for the name of their author.

**INFLUENZA.** — It is reported that influenza has appeared as an epidemic in Moscow, and that many persons are each day reported as incapacitated by it.

THE BOSTON

# Medical and Surgical Journal.

THURSDAY, AUGUST 13, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS :** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico ; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

## MICROBICIDE PROPERTIES OF THE GASTRIC JUICE : MICROBES OF THE ALIMENTARY CANAL.

In an interesting paper in the *Wratch*, Kianowski has taken up the subject of the microbes of the stomach and the effects of the gastric juice on them. To solve the question, he undertook a series of experiments on both sick and well persons. These experiments have given the following results : (1) The quantity of bacteria found in the contents of the stomach one hour after a meal is not so much in inverse relation with the acidity of the gastric juice and the quantity of hydrochloric acid therein, as it is in direct relation with the amount and kinds of micro-organisms introduced with the food ; (2) Within the limits of the mean acidity due to hydrochloric acid, the gastric juice systematically and completely kills the microbes in the stomach ; the more prolonged the action of the gastric juice, the more microbes it kills. (3) There is a general relation between the augmentation of the general acidity due to the normal or abnormal properties of hydrochloric acid on the one hand, and the quantity of destroyed microbes on the other. (4) If the acidity of the gastric juice is feeble, the microbes multiply in the stomach. (5) Experiments on sick persons have shown that if their gastric juice contains a sufficient quantity of free hydrochloric acid, it possesses the same microbicidal qualities as the gastric juice of healthy persons.

The conclusions of this important paper are : (1) In a state of fasting, the stomach of a man in good health contains a great many microbes. (2) The quantity of microbes existing in the stomach during the first hours of digestion is in direct relation with the quantity introduced with the food, drink, air, saliva, etc. (3) The gastric juice, and especially its hydrochloric acid, possesses most manifest microbicidal properties. (4) The microbes probably take no active part in the processes of stomach-digestion. (5) Persons who by reason of some disease secrete little hydrochloric acid, more easily become the victims of

poisoning by microbes or their products introduced into the stomach. (6) It is not well in the morning to remain too long a time fasting, and during epidemics such as cholera, it will not do to let the stomach become empty; the latter should always contain a certain quantity of food and, if possible, sterilized food.

It will be seen that these views are foreign to those published several years ago by Bichamp, who referred the entero-digestive process to the action of certain microbes called by him microzymes. Bichamp's theories were purely speculative, being based on Pasteur's studies in fermentations; his pretended microzymes have not been seen by any other microscopist. The older chemical theory of digestion still holds its grounds.

Van Puteren, in the *Deutsche Medizinische Zeitung*, reports the results of 127 experiments made upon 40 children, the ages ranging between three and seventy-seven days. Material for examination was obtained from the stomach by a sterilized Nelaton catheter, and examined bacteriologically.

The proportion of bacteria in the stomach was found to be greatly increased whenever the tongue was coated or deposits existed in the mouth, these being conditions in which bacteria in the mouth were most abundant. The bacteria were much more numerous in infants fed on cows' milk than on those nursed at the breast.

Of especial interest are the results which he obtained after the mouth had been thoroughly cleansed. In eighteen per cent. of the experiments made, *no bacteria* were obtained from the stomach of breast-fed children. In forty-one per cent. the proportion to the average number found in the stomach under other circumstances was as 1 to 130. In the cases in which bacteria were found to be absent from the stomach, the digestion was apparently perfect; hence the writer reaches the conclusion that bacteria have no essential physiological function in the infantile stomach.

This writer's experiments further show that the acidity of the stomach does not prevent bacterial growth. He made eight experiments to determine the acidity, and found it only .6 to .8 per cent. While Miller had shown that 1.6 per cent. acidity was necessary to inhibit bacterial growth.

It will be seen that these latter experiments hardly agree with those of Kianowski. Doubtless in healthy infants fed on unsterilized cows' milk, the action of the gastric juice is similar in its microbicidal properties to that of adults that habitually eat unsterilized food. Such infants are more likely to microbe infection through the alimentary canal than infants fed on breast-milk. And it may well be conceived that the alimentary canal of the latter will be tolerably free from bacteria, especially if the mouth be kept clean.

The influence of bacteria in abnormal intestinal processes is awakening attention, and this whole subject has been investigated of late by Baginsky, Lesage, Escherich and others. The bacteria found in summer diarrhoea are very numerous, but how far they are simple accompaniments and how far they are the

causes of morbid changes is not yet definitely determined. Certain it is that there is everywhere great interest in maintaining intestinal antisepsis in all the summer complaints of children and adults, and the results of such antiseptic treatment are sufficiently encouraging.

#### SYPHILIS IN ICELAND.

ICELAND is one of the few countries in which, according to the statements of all competent writers, syphilis does not exist. The malady is reported to have been introduced into the country from without, at several different epochs, but it has never taken root, so that the theory has been advanced that the people of this island possessed a certain immunity from the disease. Lesser, considering it highly improbable that a people differing as little from the other branches of the human race as the Icelanders do, should offer so striking a phenomenon as an immunity from this scourge, addressed a letter to Dr. Schierbeck, in Reykjavik, in which he proposed the following questions:

(1) Is it true that no syphilitic symptoms are met with among the present generations of Icelanders? (2) Do not the chronicles of Iceland, at the time when syphilis was spread over all Europe,—that is, at the end of the fifteenth and the beginning of the sixteenth centuries,—record the appearance of the disease in Iceland also?

The reply of Dr. Schierbeck, the foremost medical authority in Iceland, is interesting and not un instructive from the point of view of preventive medicine. In the course of eight years' experience upon the island, he had met with but four well-authenticated cases of syphilis in native Icelanders. This is sufficient proof that the theory of immunity is untenable. All of these cases were acquired in foreign countries, and he knows of no case occurring in people who had never left the country. This shows that syphilis is not of common occurrence, and is in no sense so widely spread as in most other countries. The question next arises why the disease, that is occasionally imported, does not spread more rapidly. The answer is found in the local conditions, the isolation of the centres of population, and the intimate acquaintance with every one living in the vicinity, which makes discovery of any importation a comparatively simple matter. The importers of syphilis may be divided into two classes, the natives and the foreigners. The natives who import the disease belong, without exception, to the upper classes, as the others have no money for travelling. If a native infected with syphilis returns to the country, his first care is to keep his disease a secret, and he does not think of marriage until a proper period of treatment has been observed. The foreigner does not find it an easy matter to come into close association with the people, and the country contains no facilities for prostitution. He regards it as not impossible that the frequency of the occurrence of syphilis may be much

augmented in the near future, when the emigrants to America begin to return in larger numbers.

Dr. Schierbeck was unable to obtain data for an answer to the second question proposed—as to the occurrence of syphilis in the fifteenth and sixteenth centuries in Iceland. It is quite probable that it may have been recorded at that time under other names, and a suspicious word, "Pletsot," frequently occurs, which demands careful study.

### MEDICAL NOTES.

**ARMY AND NAVY EXAMINATIONS.**—During the past ten years 384 candidates have presented themselves to the Army Boards, of whom 76, or 22.3 per cent. passed and 31 were rejected for physical disqualifications, and the remainder failed to pass the medical examination. During the same period, 237 candidates presented themselves before the Navy Board, of whom 55 were approved and passed, 75 rejected for physical disqualification and the remainder either withdrew or failed to pass.

**THE MEXICAN PHARMACOPEIA**, which was issued in 1884, is undergoing revision at the hands of the Mexican Pharmaceutical Society, with a view to the incorporation of new remedies which have found acceptance in the medical profession since the date of its publication.

**FOOT AND MOUTH DISEASE.**—Professor Fröhner, of Berlin, has recently published a paper in the *Zeitschrift für Fleisch und Milch Hygiene*, tending to show that foot-and-mouth disease can be transferred to human beings by means of the milk of cows suffering from it, or by means of butter made from such milk.

**THE SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY**, opened its session in St. James's Hall, in London on Monday, the Prince of Wales presiding. There were 2,500 delegates present. Among those present were Professor Pasteur, of Paris, and Professor Koch, of Berlin.

**THE SOCIETY OF GERMAN NATURALISTS AND MEDICAL MEN.**—The sixty-fourth meeting of this Society will be held in Halle from September 21st to the 25th. Professor Nothnagel, of Vienna, will speak on "The Limits of Medical Art;" Professor Ebstein, of Göttingen, on "The Art of Prolonging Human Life;" and Dr. Ackermann, of Halle, on "Edward Jenner and the Question of Immunity."

**THE TARIFF AND OPTICAL INSTRUMENTS.**—The Cincinnati *Lancet-Clinic* calls attention to an advertisement in the *Ophthalmic Review*, published in London, of a very old firm of opticians in Philadelphia, which is noteworthy on account of its closing sentence. It is an offer to furnish a set of trial lenses for \$60 (60¢) excepting in the United States where the price is \$75.

**HYGIENE ADVANTAGES OF THE ELECTRIC LIGHT.**—Referring to a statement which has been publicly

made that the adoption of electric lighting in place of gas at the office of the Savings Bank Department of the General Post-office, London, has been followed by a marked reduction in the amount of sick leave, the *Lancet* says it has good authority for believing that the statement in question is substantially correct. Although the time which has as yet elapsed—two years—since the introduction of the new illuminant has been insufficient for the collection of trustworthy statistics, the paper named thinks there is every reason to believe that electric lighting will prove to be much more wholesome than ordinary gas flames. An electric lamp does not compete for the oxygen of the apartment in which it is placed, and this circumstance gives it a marked advantage over any open flame. It cannot, like some forms of gas-burner, be used to promote ventilation; but in ordinary situations its harmlessness is a much more important property.

**THE GERMAN EMPEROR'S HEALTH.**—It is reported that the German Government has deemed it necessary to issue a semi-official notice regarding alarmist reports about the emperor's health. The German newspapers have occasionally alluded to ridiculous stories of the emperor's epileptic fits, brain disorders, purulent inflammation of the ears, caries of the cranial bones, and a host of other maladies.

**THE DISCOVERY OF THE SEX OF THE FŒTUS DURING PREGNANCY.**—Dr. R. Ross says in the *British Medical Journal* that for some years he has been able in many cases, to forecast the sex of the child before birth from the position in which the mother tells him she feels most distinctly the fetal movements. Most women can, but some cannot, differentiate the locality. In those who can he finds the following rule applies with wonderful accuracy: If the mother describes the fetal movements as chiefly and most distinctly on the left side he confidently predicts a male birth; if on the right, he as surely determines the sex to be female.

**THE NEW UNIVERSITY IN LONDON.**—At a meeting of the Committee of the Privy Council on the petition of University and King's Colleges for a Charter to a new university in and for London, on July 29th, Lord Selborne announced that all the medical schools in London have now agreed to associate themselves with the medical faculties of University and King's Colleges to form the medical faculty of the proposed new Albert or Metropolitan University. The Royal Colleges have declined to be represented on the Council. Owing to delays, entailed by the necessary forms of procedure, the new university cannot come into existence before February, 1892, at earliest.

**BRITISH INSTITUTE OF PREVENTIVE MEDICINE.**—In consequence of an influential deputation of medical and scientific men, Sir Michael Hicks-Beach, President of the Board of Trade, has granted the required license to register the British Institute of Preventive Medicine as a limited liability company,

with the omission of the word "limited." The license, however, is not to be construed as implying approval by the President of the Board of Trade of experiments on animals. The articles of association were duly signed on July 21st, at Sir Joseph Lister's residence. Among the signatures are those of Sir Joseph Lister, Sir Spencer Wells, Sir Henry Roscoe, Sir George Humphrey, Mr. Watson Cheyne and others. The official license has also been received. The granting of the license had for some time been opposed by antivivisectionists.

CONGRESS FOR THE STUDY OF TUBERCULOSIS. — On July 27th, this congress was inaugurated by a visit to Professor Lanoulongue's wards at the Hôpital Trousseau, where the cases treated according to the new chloride of zinc method were passed in review. Later, the first meeting was held at the Faculty of Medicine under the presidency of the veteran Villemin. About 400 members were present to listen to addresses by Professors Verneuil, Grancher and Arloing. The latter inquirer gave experimental proof of the inefficiency in the laboratory of Koch's tuberculin. Meetings were held on the 28th, 29th, 30th and 31st, and visits were paid to Professor Verneuil's wards at the Hotel Dieu, where patients treated by injections of iodoformed ether were presented; to the Val-de-Grâce Military Hospital, to see cases treated by injections of creasoted oil; and to the Institut Pasteur. A grand banquet took place on Thursday evening. In connection with this subject, the *Progrès Médical* revives the question of the disinfection of railway carriages employed for the conveyance of phthisical visitors to the southern health resorts. Frausnitz is quoted as having examined the dust of *coups* on the express train doing the service between Berlin and Meran — a route much frequented by consumptives. He inoculated this dust into guinea-pigs according to the serial method of Cornet, and found that two out of five *coups* contained the tuberculous bacillus. The journal above mentioned urges the Paris-Lyon-Méditerranée Compagnie to provide — at least, for the better class travellers — antiseptic spittoons.

#### BOSTON AND NEW ENGLAND.

DEATH-RATE OF BOSTON. — During the past week the number of deaths in Boston was 209, a mortality of 23.6. This is less by 69 than occurred during the corresponding week last year. The number of deaths reported as due to cholera infantum was 48, whereas during the previous week it was 92.

RECENTLY APPOINTED MEDICAL EXAMINERS IN MASSACHUSETTS. — A list of medical examiners appointed by Governor Russell previous to July 1st will be found in the JOURNAL of June 25th. The following is a list of those since appointed with their residences. Most of them are reappointments. July 8th: William A. Dolan, Fall River; Richmond B. Root, Georgetown; Charles A. Carleton, Salem; A. Elliot Paine, Brockton; George L. Ellis, Middleborough; Benjamin H. Hartwell, Ayer. July 16th: Patrick

Henry Keefe, Worcester; Dyer B. N. Fish, Amherst; Christopher Seymour, Northampton; Henry A. Jewett, Northborough; John C. Irish, Lowell; Charles C. Holcombe, Lee. July 23d: Erastus C. Coy, Montague; Andrew H. Hodgdon, Dedham; George S. Osborne, Peabody. July 30th: Edgar D. Hill, Plymouth; David W. Miner, Ware; Thomas H. O'Connor, Clinton; John D. Kiely, Fitchburg; Walter M. Wright, Orange; Charles A. Bemis, Medway. August 6th: Garry de N. Hough, New Bedford; Harry M. CUTTS, Brookline.

A BEQUEST TO THE RHODE ISLAND HOSPITAL of about \$70,000 is contained in the will of John W. Smith, recently offered for probate.

#### NEW YORK.

THE AMBULANCE SERVICE. — A commission having been appointed by the Grand Jury to make an examination of the ambulance service in the city and to offer suggestions with a view to increasing its efficiency, the report of the commission was last week read in the Court of General Sessions. Regarding the private hospitals — the New York, with its Chambers Street Branch, St. Vincent's, the Roosevelt, the Presbyterian, and the Manhattan, the commission states that it found the ambulance equipment and service such as to call for approval. The ambulance surgeons are all graduates of medicine and are not detailed for this service until after they have had six months' active duty in the hospital wards. The private hospitals have twelve ambulances.

The Commission denies that patients are transferred from these hospitals to Bellevue to diminish their death-rate. Such transfers as are made, the commission is satisfied, are proper and necessary. In the report a table is given showing the number of ambulance calls attended by the different hospitals during the year 1890. St. Vincent's had 1,930 calls; the Manhattan, 567; Chambers Street, 2,678; the Presbyterian, 1,202; the New York, 1,321; and the Roosevelt, 1,530. Of the public hospitals, Bellevue had 4,246 calls; Gouverneur, 2,374, and Harlem, 1,225. These three hospitals have ten ambulances.

The report urges the Department of Charities and Correction to hasten the establishment of the proposed Fordham Hospital for the relief of the upper east side districts, and also recommends the establishment of a hospital and ambulance service on the west side of the city between Roosevelt Hospital (59th Street) and Manhattan Hospital (at 131st Street). Fear is expressed by the Commission that cable roads in crowded streets will cause many more accidents during the first year or two of their use, and the report urges that its recommendations should be attended to at once. "While," continues the report, "we find very much to commend regarding the response by all hospitals to ambulance calls upon them, we are compelled to criticize very generally the present lack of adequate official means of conveying prompt notification to the hospitals of the necessity for an ambulance at a location

where some one may be suffering." The report then goes on to say that it is a discredit to the city that it should still be without a comprehensive system of signal boxes or stations scattered through the streets in large numbers by which an ambulance can be summoned. The Commission would, therefore, urge the Police Department to secure, without delay, the most approved and perfect system available for rapid communication with station-houses, both for police purposes and ambulance service. It also urges the Board of Estimate and Apportionment to appropriate immediately the money required for this object.

### Miscellany.

#### A LAW FOR THE PREVENTION OF BLINDNESS.

FOLLOWING the example of the State of New York, where a similar law was passed in 1890, the State of Maine has passed the following law, which was approved by the governor on March 28th:

SECTION 1. Should one or both eyes of an infant become reddened or inflamed at any time within four weeks after its birth it shall be the duty of the midwife, nurse or person having charge of said infant to report the condition of the eyes at once to some legally qualified practitioner of medicine of the city, town or district in which the parents of the child reside.

SECT. 2. Any failure to comply with the provision of this act shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months, or both.

SECT. 3. This act shall take effect on the first day of June, eighteen hundred and ninety-one.

#### THE ARTIFICIAL PRODUCTION OF DENTAL CARIES.

For the past year Mr. Sewill, following other experimenters in the same field, has been endeavoring to produce caries in extracted teeth; and certainly the microscopical appearances presented by the sections shown at the Odontological Society, says the *Lancet*, differed but little from those of natural caries.<sup>1</sup> He found that the best mixture of organic substances for the purpose was one part of bread to eight of saliva. Meat with saliva remained alkaline, and if a small quantity of acid were added became again rapidly alkaline. Albumen, whether as white of egg or other forms, acted in the same way. Saliva and starch produced little acid, which was soon exhausted.

The teeth were immersed in the mixture in glass-stoppered bottles, and kept at a temperature of 35° to 37° C. The bottles were unstopped about once a day for examination; this, of course, admitted air, and if the mixture became putrid, it at once showed an alkaline reaction, in which case the teeth were taken out, well washed, and the mixture renewed. The mixture became rapidly acid, and remained so (unless putrefaction to a large degree supervened) for from three to five weeks. The acids present were acetic and lactic; of the former five per cent. and of the latter one-half per cent. were found after three weeks. The effects upon the tissue were precisely the same, both microscopical and metacopical, as in natural caries.

As in natural caries, the decay was found to commence most readily in places where there was ill-formed enamel or flaws or fissures which allowed access to the dentine, in which tissue the caries progressed more rapidly than in enamel. Cementum resisted longer than enamel, but at length yielded, and allowed the dentine beneath to be invaded. Discoloration was often present, and it was found that carious dentine readily took up stains from such substances as are often admitted to the mouth in medicines or articles of food. Microscopically the translucent zone is well shown, also the "pipe-stems" appearance in transverse sections, and the dentinal tubes are filled with micro-organisms, just as in natural caries.

The conclusions that Mr. Sewill draws from these experiments, and from the fact that caries takes place in natural teeth which are used as artificial substitutes, are, that caries is entirely due to external agents, and that vital action in no way modifies the disease.

#### BRONCHO-PNEUMONIA.

MOSBY,<sup>1</sup> in a paper on the lesions, causes and prophylaxis of broncho-pneumonia, concluded as follows:<sup>2</sup> Broncho-pneumonia is an acute specific inflammation of the bronchioles and lobules which are involved.

Whatever be primary or secondary, and whatever be the lesion which has preceded, the lesions of this disease differ in the different cases only by the variations of a process which is always identical.

Only the duration of the broncho-pulmonary inflammation or the virulence of the pathogenic agent can account for differences observed in the appearance of the histological lesions.

The lesions, according to their topographical arrangement, show two distinct types: a lobular type, due to the action of the streptococcus pyogenes and alone constituting true broncho-pneumonia, and a pseudo-lobular type, due to the pneumococcus lanceolatus of Talamon-Frankel, which should be distinguished from broncho-pneumonia and classified with simple pneumonia, of which it is a particular form, occurring among children.

The gravity of the disease, which is almost the same for all ages, should be considered as follows: (1) In the adult, owing to the rapid generalization of the pulmonary infection. (2) In children, owing to the constant presence of extensive accessory mechanical lesions, atelectasis and emphysema, which narrow the field of hematosis and cause death from asphyxia.

Broncho-pneumonia is epidemic and contagious. The only way to prevent its propagation is to practise antiseptics in isolation wards for infectious diseases with which it is constantly complicated.

#### A RECENT DECISION IN A SUIT FOR MALPRACTICE.

THE Appellate Court of Illinois has recently affirmed the decision of the Cook County Circuit Court in favor of the defendant in the case of *Sims vs. Parker*.<sup>3</sup> The plaintiff Sims, had been wearing, upon

<sup>1</sup> Rev. Mens. des Mal. de l'Enf. March.

<sup>2</sup> Archives of Pediatrics, August.

<sup>3</sup> Journal of the American Medical Association, August 1st.

a physician's advice, a truss on the left side as a preventive for hernia. This was prescribed because of a pain which he felt in the left inguinal region in 1881. In March, 1888, he applied to Dr. Parker, who is a dealer in trusses, for relief from a similar pain on the right side. On examination Dr. Parker found an inguinal swelling, which he pronounced a hernia, and fitted Sims with a double truss. From the beginning Sims complained of the pain of the truss, but continued to wear it for about a month, when he became feverish and went to bed. He was confined to his bed about three weeks, at the end of which time the inguinal swelling had become as large as an egg, and in three weeks more had developed into an abscess seven inches long, the contents of which were evacuated by his attending physician, Dr. Snyder. Subsequently another abscess formed.

The contention of the plaintiff was that the truss had been improperly applied, and had produced the abscess.

At the close of the evidence the Court directed the jury to find a verdict for the defendant. The decision of the court contains the following:

The physician who attended plaintiff and who was a witness on trial, was unable to say whether there was an incipient abscess at the time the truss was first adjusted, or whether the abscess was produced by the pressure of the truss. The fair result of the evidence of the experts sworn is, that there was in fact no rupture on the person of plaintiff, but it is also proven that it is very difficult to tell, with certainty, in many instances, whether in fact there is hernia or not, particularly in the case of fleshy persons. Defendant introduced a number of leading surgeons and physicians of the city, who testified to the reputation and skill of defendant in treating hernia, and in fitting and adjusting trusses.

While there is evidence tending slightly to support the contention that the abscess may have been produced by the pressure of the truss, there is absolutely no evidence that defendant was negligent or unskillful in his diagnosis or in fitting the truss. Proof that he was mistaken as to the existence of a rupture, or that the abscess was caused by the pressure of the truss, was not enough to entitle plaintiff to a verdict.

Proof of a bad result or of a mishap is of itself no evidence of negligence or lack of skill. The defendant is qualified to practice medicine and surgery, and the evidence of the experts in his profession shows him competent and skillful. Before a recovery could be had against him, it must be shown that his treatment was improper or negligent, not merely that he was mistaken, or that his treatment resulted injuriously to plaintiff. A physician or surgeon, or one who holds himself out as such, is only bound to exercise ordinary skill and care in the treatment of a given case, and in order to hold him liable, it must be shown that he failed to exercise such skill or care.

### THERAPEUTIC NOTES.

**BUTTER AND OLEOMARGARINE.** — The *Medical and Surgical Reporter* gives the following ready test for differentiating these substances: Dissolve 25 parts of silver nitrate in 100 parts of alcohol of 95°. Put some of this solution in a test-tube, and melt and add a portion of the material to be tested. Agitate for a

few moments, and let stand. Pure butter retains its natural color, while the margarine will become a dirty brick red, the color of a mixed sample depending upon the quantity of the adulterant present therein. The test is said to be sufficiently delicate to detect five per cent. of margarine, while with ten per cent. the color reaction is very strong.

Make an emulsion.

**ARISTOL IN IVY POISONING.** — Dr. J. J. Levick² reports a case in which severe poisoning from rhus toxicodendron was promptly much relieved by the free dusting of powdered aristol on the affected parts.

**HYDRATIS CANADENSIS FOR NIGHT-SWEATS.** — Cruse has used the fluid extract of hydratis canadensis with very good results in the night-sweats of phthisis.³ He gives it in doses of thirty minims, and often finds that the dose does not have to be repeated for some time.

**CAFFEINE IN PNEUMONIA.** — De Gempt urges the use of caffeine in cases of threatened collapse in various asthenic diseases, but especially in acute pneumonia, and cites several cases in which it was successfully used in conjunction with stimulants.⁴ He believes the drug indicated in the course of acute pneumonia when there is evidence of cardiac failure, such as rapid, irregular pulse with lowered tension. Should the pneumonia be of asthenic type, it should be used from the onset, and the earlier in the course of the disease it is used after asthenia develops, the better. In cases of this sort, caffeine, in doses of .35 gramme four to five times daily, raises the arterial tension, diminishes the rate of the respiration and pulse, and lowers the temperature. Its action is prompt, but in urgent cases it had better be used hypodermically. It is advisable to continue it for a brief period after the febrile defervescence.

Deaths reported 3,392; under five years of age 1,858; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 1,145; consumption 500; acute lung diseases 156; diarrhoeal diseases 864; diphtheria and croup 12; typhoid fever 73; scarlet fever 40; whooping-cough 27; measles 21; cerebro-spinal meningitis 16; malarial fever 9; erysipelas 2; puerperal fever 1.

From scarlet fever New York 19, Chicago and Brooklyn 6 each, Philadelphia 4, Cincinnati and Milwaukee 2 each, Lynn 1. From whooping-cough Pittsburg 19, Philadelphia 7, Milwaukee 3, New York and Brooklyn 2 each, Chicago, Nashville, Lynn and Springfield 1 each. From measles New York 10, Chicago and Brooklyn 3 each, Philadelphia, Pittsburg, Milwaukee and Cambridge 1 each. From cerebro-spinal meningitis Chicago 3, Boston and Worcester 2 each, New York, Philadelphia, Brooklyn, Milwaukee, New Bedford, Malden and Quincy 1 each. From malarial fever New York 5, Brooklyn 3, Charleston 1. From erysipelas Pittsburg and Brooklyn 1 each.

In the twenty-eight great towns of England and Wales with an estimated population of 9,195,108, for the week ending July 18th, the death-rate was 17.5. Deaths reported 3,152; acute diseases of the respiratory organs (London) 189, diarrhoea 166, whooping-cough 29, measles 67, diphtheria 26, scarlet fever 20, fever 16.

The death-rates ranged from 8.8 in Derby to 24.5 in Liverpool, Birmingham 17.9, Bradford 15.9, Hull 20.2, Leeds 17.2, Leicester 1.2, London 17.9, Manchester 18.4, Nottingham 12.3, Sheffield 16.0.

In Edinburgh 17.1, Glasgow 17.7, Dublin 16.1.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 1, 1891, TO AUGUST 7, 1891.

First Lieutenant ALFRED E. BRADLEY, assistant surgeon U. S. A., granted leave of absence for thirty days.

The leave of absence granted Assistant Surgeon WILLIAM L. KESSELER, U. S. A., is extended one month.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 8, 1891.

R. A. MARMION, surgeon, detached from Navy Yard, Norfolk, and to the Navy Yard, Boston.

G. F. WINSLOW, surgeon, detached from Marine Rendezvous, Boston, and to the Navy Yard, Norfolk, Va.

J. B. PARKER, surgeon, detached from Navy Yard, Boston, and placed on waiting orders.

F. G. BRAITHWAITE, assistant surgeon, ordered to Receiving-ship "Walsh," at Navy Yard, Boston.

J. B. URIE, assistant surgeon, detached from Receiving-ship "Walsh," and to the Marine Rendezvous, Boston.

F. J. B. CORREIRO, passed assistant surgeon, detached from Naval Hospital, Chelsea, Mass., and granted two months' leave of absence.

G. MCC. PICKERELL, passed assistant surgeon, from Hospital, New York, and to Hospital, Chelsea.

## SOCIETY NOTICES.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. — The fortieth meeting of the Association will be held in Washington, beginning with the council meeting on Monday, August 17th. As there will be meetings of several affiliated societies about the time of the Association meeting, and as the International Congress of Geologists will hold its first meeting in this country during the last week in August, the official time given for the Association meeting will be from August 17th to September 2d. This will allow members of the Association to unite with and attend the meetings of the other societies.

F. W. PUTNAM, *Permanent Secretary*, Salem, Mass.

THE TRI-STATE MEDICAL ASSOCIATION OF ALABAMA, GEORGIA AND TENNESSEE will hold its third annual meeting at Chattanooga, Tenn., October 27-29th.

W. L. GAHAGAN, M.D., *Secretary*, Chattanooga.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION. — The annual meeting will be held in St. Louis, October 14-16.

I. N. LOVE, M.D., *Chairman Committee of Arrangements*.

## DEATHS.

HORACE DUFER, M.D., M.M.S.S., died in Dorchester, August 7th, aged eighty-one. He graduated from Harvard College in the Class of 1852, and from the Harvard Medical School in 1857.

RICHARD LEE MACDONNELL, M.D., Professor of Clinical Medicine at McGill University and Physician to the Montreal General Hospital, died July 21st, aged thirty-five.

DR. JOHN SUTHERLAND, one of the pioneers of hygienic progress in England and author of numerous official reports on matters concerning the public health, died July 14th, aged eighty-two.

## BOOKS AND PAMPHLETS RECEIVED.

Des Glycosuries non Diabétiques. Par G. Halsted Boyland. Paris: Henri Douvier. 1891.

Illustrated Cases of Congenital Club-Foot. By H. Augustus Wilson, M.D. Reprint. 1891.

Arsherättelse fran Sabbatsbergs Sjukhus, Stockholm. Afgifven af Dr. F. W. Warfvinge. 1891.

Transactions of the Medical Society of the State of New York for the Year 1891. Published by the Society.

The Remarkable Effects of Diuretic in Removing Dropsy. By Robert H. Babcock, A.M., M.D., Chicago. Reprint. 1891.

Linear Craniotomy for Defective Mental Development. By William H. Morrison, M.D., Philadelphia, Pa. Reprint. 1891.

Session 1891-92. Annual Announcement of the New York College of Veterinary Surgeons and School of Comparative Medicine, Chartered 1857.

The Varying Significance of Intermittent Albuminuria. Report of Autopsy of a Case. By John Winters Brauman, M.D., New York. Reprint. 1891.

Report of Progress in the Treatment of Thoracic Abscesses. Traumatism of the Chest. By J. McFadden Gaston, M.D., Atlanta, Ga. Reprints. 1890, 1891.

## Lecture.

NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

(Continued from No. 7, page 157.)

*Two Special Conditions resulting from Changed Sensations.*—The more greatly altered sensations, when localized and limited, may be estimated correctly, while the more general and pervading ones cannot be so well corrected. There are two prominent conditions due to changes in these general sensations that are of the highest clinical importance in neurasthenia.

The first of these conditions is "morning depression" or "morning tire." It is sometimes called "morning misery," but the tire is the essential fact. Both the mental feelings and the common sensations are altered by increase of intensity, and measurably represent the truth as to the bodily condition, although they still appear contradictory and lead to mental error. For example, a patient having fairly comfortable feelings during the latter half of the day and in the evening, sleeps more or less well till the early hours of the morning. But on awaking he is in the depths of depression. Instead of being refreshed by sleep, all his feelings of inadequacy, misery and hopelessness are then at their keenest. The physical signs of exhaustion are more manifest. The patient feels added alarm because the sleep has not done him any good in the natural way. After breakfast he feels better, and by the middle of the forenoon his circulation is again active and steady and perhaps accelerated. The press of business and the daily interests are stimulating, and his nerve-cells, while probably giving out as much as they are taking in of energy, are evidently better nourished than in the nocturnal condition of functional inactivity. This symptom is significant by its daily recurrence. It is among the leading ones of neurasthenia; and it may occur in all degrees, from the morning feelings of being unrefreshed, to a recurring sense of misery and despair that prompts to suicide. The physician should detect this symptom of morning tire and depression, which appears early in the disease, and should not be misled by the patient's sense of comfort. The morning more nearly represents his true condition.

This symptom of "morning tire" has long been observed in melancholia, but it is now being better explained as evidence of neurasthenia. The "mechanism" of these phenomena of "distressing awakening," is most complex and involves the problems of the physiology of sleep, the rhythm of nocturnal rest and relaxation and daily activity, and the "pathology of night," of which interesting studies are of late being made.<sup>2</sup> A valuable bibliography of the subject is given by Ch. Féré.<sup>3</sup> Broadbent<sup>4</sup> says, "It is in the early morning that depression of spirits is liable to be at its worst in nervous debility, so called; or there is the morning headache which is relieved by the bath and breakfast, or wears off as the day advances; or the subject of this affection is more tired on waking up than on going

to bed." Haig<sup>57</sup> says he has "no difficulty in proving that it is just in these early morning hours that the excess of uric acid in the blood is greatest, and its effects on arterial tension most marked." Uric acidemia, in its relation to disorders of the circulation and to irritability, languor, and depression, certainly invites careful inquiry.

The significance of these tired wakings is very great, as a symptom of morbid sleep which may be due to a variety of causes, involving particularly the weakness of functional power, through its exhaustion or annulment by toxic influences as in neurasthenia.

The other special condition is that of *anæsthesia of the sense of fatigue*. It results from altered organic sensations; and the truth as to the bodily state is obscured by the change or absence of certain data of sensation that go to make up a man's judgment of himself. The indications are paradoxical and misleading.

In the example of morning tire just mentioned, the excessive work and worry might go on with increase of cerebral or general exhaustion; also the mental misery of the morning might be continued. Then a strange phenomenon may happen. The patient, who has before complained of his fatigue, now says he does not feel tired. He may have no definite sensations of inner discomfort from dyspepsia, constipation, etc., although the general miserable feelings will continue with lessening or disappearance of the evening recuperation. Still, he claims that he is not tired,—that there is nothing the matter. His attention is more and more concentrated upon the objects that have habitually interested him, or upon his morbid ideas, with lessening power to turn from them. Thus the process goes on in its vicious train.

This is one of the commonest of all symptoms, and often appears early and in slight degrees. It represents the descent of the patient's condition towards the depths of nervous exhaustion, and to a point where the sensory power itself is materially lessened. The patient, previously guided by the sense of fatigue in desisting from effort, has now lost his guide,—his natural feeling. He cannot believe his physician or his friends that he is over-tired. He is conscious of inefficiency, mental and physical; and he feels added self-reproach because he cannot accomplish what he ought when he does not feel sufficiently ill or fatigued to justify relaxation from duties that are pressing, or seem so to him. The stimulation of change, travel, etc., is often prescribed when there is fictitious appearance of the patient's ability to bear it. Tired women will carry on their domestic duties by "working on their nerves," or walk for miles without natural fatigue, seeking health in "exercise" when it is most damaging. This symptom comes out most clearly in cases that have advanced to melancholia, but it is a true index of the neurasthenic state in all its stages, and has its lesser forms in many of the milder cases. In the extreme cases the lifting up of such patients from the depths of exhaustion is a most interesting process to watch, when they "come to the sense of feeling." If previously agitated, restless and apparently fatigued, they grow more quiet,—sometimes they take to their beds with a profound sense of weakness. They say they feel worse, and are alarmed as well as their friends; but they are really better. This is a distinct stage in the upward progress toward recovery.

The conditions of melancholia, in its most neurasthenic

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.

<sup>2</sup> See Macfarlane, *Lancet*, vol. I, 1891, p. 824.

<sup>3</sup> *Art. Pathology of Night*. *Brain*, Oct. 1889, p. 308.

<sup>4</sup> *The Pulse*, p. 76.

<sup>57</sup> *Loc. cit.*

thetic stages, are among those in which this symptom of change of the sensations that go to make up the sense of fatigue is most plainly declared. In one class of cases there are the conditions of diminished sensitiveness, dulness or languor, affecting in different degrees both sensory and mental activities even to the degree of apparent or real stupor, in which the motor paresis is so striking a symptom. There is in these cases a manifest consistency in the presence of a blunting effect upon the sense of fatigue. It seems consistent enough also in that class of cases in which there are the associated symptoms of mental agitation, irritability and restlessness as manifestations of hyperæsthesia, that are continually prompting the patient to motor activity,—just as analgesia may exist with a hyperæsthesia which itself is attended by a diminution in delicacy of touch. It is, of course, true that the attention plays its part in the matter,—the attention being occupied by intensified ideas and emotions either of pleasure or of pain, there may be, for the time, an unconsciousness of the sense of fatigue that might be felt if attended to; so it is in hypnotism, or when convulsions are not perceived in a foot-ball scrimmage, or even fatal wounds in battle by men who live long enough to tell of them. But this fact does not militate against the validity of clinical observations and confessed experiences in the cases of many intelligent patients in whom the condition is of long continuance. In the extreme cases of agitation and restlessness as is well known, the patients will walk and walk by the hour, sleep fitfully, turn in their beds or leave them many times, often restlessly changing their positions by day and by night. Like symptoms of restlessness are observed also in many cases of neurasthenia without the mental symptoms requisite for diagnosis of melancholia, but both these classes of patients often declare the absence or blunting of the sense of fatigue. It should be understood that these references are made to melancholia because it presents this symptom in so pronounced a way as to reveal its importance, and something of its nature; its recognition in its lesser manifestations in neurasthenia thus becomes easier.

This phenomenon appears in cases presenting such early stages as those described to illustrate the genesis of pathological fatigue. There is evidence of this peculiar symptom in the graphic statement, quoted from the physician who felt excessive tire and the "letting down of spirits" as soon as his work was reduced to one-half of that he had just previously been doing. All the conditions of the "fatigue" were undoubtedly present before the "letting up of work" in which the exciting stimulation to activity possibly created peculiar toxic products which obscured the real conditions. At all events, in such conditions as these and the equally common experience of the "second-day tire," there is that state of pathological fatigue which is marked by a notable absence of a due sense of tire. It is certainly obvious, as a physiological fact, and as a clinical observation, as in the illustrative cases, that the degree of bodily and mental fatigue is not measured by the feeling of it. It is one of the most familiar of all familiar facts that men and women are continually over-doing themselves without knowing it. When a condition of pathological fatigue is established, this anaesthesia of the sense of fatigue, in some degree, becomes a part of the general condition. It is important to recognize it,—to give it a name,—to teach the patient to understand it,—and then its great value

as a diagnostic guide to treatment will appear. Knowledge of it also has often the happiest effect upon the patient in gaining that condition which Mitchell sought before the best treatment could be begun,— "the absence of thought with the friction of worry which injures." The patient being at fault in attempting to judge of himself by his altered and blunted sensations, is always alarmed at the mystery of his anomalous and contradictory feelings. With the feeling of inadequacy from a sense of abated motor power there is exhaustion also of sensory power. An intelligent patient always understands when told that there is tire, not only in the power to do things, but in the power to feel the tire. An apparent mystery is readily cleared up by this explanation, because it so fits the patient's experience. Then he can see the force of the rule that he must limit his exercise by quantity and time and not by feeling.

In the wide range of conditions from the milder to the severer stages, they are constantly presenting paradoxical phenomena, as they may well do, when the one neurasthenic cause is the basis alike for anaesthesia and hyperæsthesia and all their attendant trains of symptoms which are apparently so contradictory. Not in all cases does this anaesthesia of the sense of fatigue appear, nor always in like associations with other symptoms. There are different classes of cases also according to temperament, character, and habit. Women with the "New-England conscience" need always to be held back against over-effort, and too early effort in all stages of the disease, particularly of convalescence. Whether or not in the course of the neurasthenia there has been a middle period of melancholia, or the like, the principle is always the same. Then in such cases, in the condition of relative comfort and exhilaration which makes the delight of the period of convalescence, there is always danger of over-exertion. The sense of fatigue not being fully recovered, it is at one time felt and again lost, as a sequence of some indiscretion in exercise—some over-stimulation of emotion, either pleasurable or painful. This is the time for the greatest caution. But when at least the patient feels naturally tired, even though upon moderate effort, and can appreciate the restfulness of repose, then is convalescence assured if conducted with care within the limits of the recovered energy.

This analysis and estimate of the clinical manifestations of neurasthenia go to show how gravely significant and dangerous is the condition which is represented by the symptom of diminished sensitiveness, or anaesthesia of the sense of fatigue. Immediately concurrent with the induction of pathological fatigue, with its dual elements of diminished energy and auto-intoxication, almost the very first effect of these is to begin the annulment of the sense that prompts to the conservation of nervous energy. When this peculiar and very common effect is produced, the greater the exhaustion the less the direct sense of it through the normal channels. The patient vaguely feels a lessened adequacy to effort of body or mind,—a lowering of the emotional tone,—many sensations of misery as emphasized in the morning tire,—much irritability and restlessness,—and all the changes characterized as hyperæsthesia, paræsthesia and anaesthesia; in like manner there is alteration of the sense of fatigue, in some of its complex elements.

There is another class of cases in sharp contrast

with the type just described. They have usually been long ill and have developed secondary conditions. Rest being at last enforced, by the completeness of the break-down, or becoming a habit by indulgence, the rest treatment is sometimes carried too far, probably beyond the point where exercise should begin. This is a point difficult to determine, but the positive gaining of weight is a good guide. But in the condition of the prolonged "bed-cases," or in the relapsing cases, there is likely to come, when they grow fat and when they do not, a state in which fatigue is keenly felt. As an extreme manifestation of this is the inability to sit upright, to hear reading or talking, etc.; even the slightest muscular exertion, as the raising of an arm, is distressing, and there is great sensitiveness to sound or light. There is not only "horrible depression" upon slight exertion, but a "terrible exhaustion." The quickened pulse, palpitation, change in color, etc., are physical signs in proof of great weakness in such cases. This appears, indeed, like hyperæsthesia of the sense of fatigue in some of its complex elements; but when these cases are led to convalescence, it is long before the natural sense of fatigue, and resistance to its quick disturbance, is recovered. With the dyspeptic aversion to food, the weakened power of assimilation of what is taken, the discouragement of many relapses, and all the effects of habit, these cases are difficult enough.

The mechanism of the sense of fatigue is obscure, as is the complexity of its origin. The difficulty of distinguishing between the central nervous fatigue and the peripheral fatigue of muscles has been noted. The central sense of innervation, and of the need of increasing effort with the increasing fatigue, would seem to be necessarily an element in it. But this very mental activity of brain cells is assumed to yield, along with waste products and work, the organic sensations of fatigue. Again, the same is true of the muscular sense, or sense of weight, as affording sensations of work being done, of exhausted energy, or of disability of contractile power. But the muscular sense is said to belong rather to the special senses, and we see it still acting normally in the cases of pronounced fatigue-anæsthesia, when there is no marked ataxic change of muscular coördination, even in very restless and irritable cases. It is, indeed, but a question of the degree of alteration of the muscular sense? With doses of alcohol, ether, and the like, we may first blunt the sense of fatigue, then more and more the sense of weight, even to its annulment as the necessary element in coördination of muscular movement, and the result may be the ataxy of intoxication. In the transitions between these first and last stages of changed sensations, as the effect of one and the same poison, does the common phenomenon of the anæsthesia of the sense of fatigue in neurasthenia represent but a first stage, as a peculiar effect of some special poisoning? We have not as yet, in the study of these pathological conditions, the data of experimental study to demonstrate the mechanism of this symptom. But we have certainly the final fact of its clinical manifestation, and it stands the test of the practical application of this explanation of it.

With this additional study of these alterations of organic sensations, the way is prepared for a characterization of them in a summing up of the symptoms of neurasthenia. Three orders of these symptoms have been set down; the fourth should therefore include

those relating to the alterations of sensitiveness, both in the direction of anæsthesia and hyperæsthesia, and should present the conclusions drawn from this last analysis and estimate of them. The following statement, then, is meant to include, in their four orders:

*The Subjective Symptoms of Neurasthenia.*—(1) Depression of spirits,—lowering of the emotional tone and a sense of ill-being. (2) Decrease of the power of attention (reflex attention), and sometimes of memory. (3) Morbid introspection, retrospection and apprehension (worry hypochondria). (4) Diminished sensitiveness, dulness and languor (anæsthesia); irritability and restlessness (hyperæsthesia).

These minor orders of symptoms go to make up a symptom-group that forms a clinical picture of neurasthenia, covering the elements of many possible variations of its forms. The sources and mechanism of each order of symptoms have been studied, and this should furnish the data for a precise definition of the disease. That of Dana has already been amended, in these pages, to include the element of languor that represents the fundamental element of toxic blunting of sensitiveness; and while this, and the specification of excessive weakness and irritability, imply a mental element, the prime importance of this, as early recognized by Beard and Mitchell, is not adequately noted. On the basis of the foregoing summary of symptoms the amended definition may be written as follows: *Neurasthenia is a morbid condition of the nervous system, and its underlying characteristics are excessive weakness, and irritability or languor, with mental depression and weakened attention.*

*Diagnosis.*—Neurasthenia being regarded as a condition of the nervous system, manifested by functional disorder and without structural changes being as yet demonstrable, and presenting symptoms of so many variable phases, its determination as a disease is peculiarly limited to the method of exclusion. It is not only a direct result of stress and wear on the one hand, but it is so constantly secondary to debilitating influences of all kinds,—the "general debility" of our fathers in medicine,—that it has often to be differentiated as being the remote and not the immediate effect or symptom of some antecedent disease. In other words, such a disease may pass away and leave the nervous symptoms to continue as if somewhat by habit. On the other hand, it is the initial condition and often the sole basis of a great variety of symptom-groups, which are framed into pictures of "clinical entities"; it must therefore be differentiated from those disorders of the nervous system in which something has been added to the simple neurasthenia, of graver functional disturbance and perhaps of definite structural change.

Neurasthenia often stands as a middle term between general etiological conditions and nervous disorders. It simplifies and clarifies the view, to regard neurasthenia as the common etiological and initial term to many varieties of symptom-groups, and even of definite nervous diseases, about which there is so much confusion as to their etiology. This is peculiarly true of mental diseases with which we cannot yet get beyond a classification of symptom-groups.

The nutrition of nerve-cells being primarily at fault, toxic influences being always primarily present, central disorder of the nervous system being usually manifested by the earliest symptoms, and cerebral exhaustion through mental strain being one of the most common forms, the diagnosis must often be made solely upon

the subjective and mental signs. This may be done early enough for prophylaxis in many cases. Any notable and persistent alteration from the natural manner and appearance, indicating a lowering of the emotional tone, in persons otherwise in apparent good health, suggests inquiry as to the cause of the abatement of natural vivacity and the lack of the usual mental control manifested by unwonted irritability of temper which may be confessed. These premonitory indications are of the most practical value. Active professional and business men who do much brain-work and incline to sedentary habits, women under a monotonous strain of domestic life or subjected to special mental anxiety and grief, or the indolent who suffer especially from functional disuse and defective elimination, all, at times, are likely to experience these mental signs of "fatigue" and toxicity. The primary order of symptoms being present, and the causes continuing, some of those of the other three orders that have been specified will soon be manifest in some slight degree, and be more or less slowly developed. The study of the genesis of these subjective symptoms and their nature as summed up in the foregoing section, may serve to show how their natural order of development affords a method of analysis that is an aid to diagnosis.

Neurasthenia should first be differentiated from the antecedent conditions, with a discrimination of its immediate and remote causes. This demands a determination, as far as possible, of the nature of the inanition and the auto-intoxication, whether partial or general, — and, otherwise, the study of the "mechanism" of the symptoms. This implies, at the outset, a careful study of all the objective symptoms by the usual methods of diagnosis. Their character as due to neuroses must be established as at least probable, to the exclusion of organic diseases of the nervous system, although these may still have a neurasthenic basis that is amenable to treatment. The inquiry is then led into the central "weakness," the diagnosis of which points out the need of general treatment rather than of medication for the localized disorders. The objective items of the most practical diagnostic importance in this regard are of two classes, and pertain to the elimination of toxic waste products, and to the processes of repair by nutrition and tonic influences.

The way is now clear for a further differentiation of the subjective or mental symptoms to determine the diagnosis and prognosis with respect to melancholia. It must be remembered that many cases of melancholia have no more than the four orders of symptoms, — no delusions, and no essential impairment of integrity of the reasoning power; — it is a question of degree. On the other hand, very pronounced manifestations of these orders of symptoms, more than in some of the cases of melancholia, will not truly bear that diagnosis, although the underlying organic conditions are of the same nature in both these types of cases. Difficult as it is to draw the line between "nervous prostration" and melancholia, the crucial test may perhaps be best stated as a question of the degree of impairment of the higher power of inhibitory control, — the weakening of the voluntary power exercised through the attention. There may come a time in these conditions when painful ideas become so dominant, because of the inability to inhibit them, as to endanger the patient by promptings to suicide. Then we say it is melancholia, and that there must be medical restraint. But

in many cases the true conditions of melancholia are established before this symptom comes. It is a matter of temperament, education, training, "habits of thought," — there are those nobler souls who withstand to the last degree the nervous exhaustion, the misery of mental pain, and the terrible temptation to seek relief through "the open." But many are weak in will and inhibition, and yield early to specious reasoning and the bias of the emotional tone, for whom recovery would be as sure as from other forms of functional weakness. But this bias of emotional tone, which more or less influences all alike, may depend exactly upon those alterations of the "sense of body" which annul the instinctive love of life, thus technically establishing the diagnosis of melancholia. The differential diagnosis of neurasthenia and melancholia, then, depends upon an estimate of the degree of nervous exhaustion with reference to the mental symptoms, particularly as to depression of feeling and weakened inhibition. This estimate must include a judgment of the individual as to character and of the probable continuance or increase of the alterations in the organic sensations as affecting the natural instinct of self-preservation. Such alterations become the basis of a fifth order of symptoms which complete the symptom-group that constitutes a typical melancholia.

The physical or objective signs do not afford a good differential guide as between neurasthenia and melancholia. The latter may exist without more pronounced symptoms of general debility, disorders of digestion, etc., than are common to neurasthenia, although they are often seen in melancholia, as anemia, a sub-normal temperature, and a urine which may be scanty and condensed, etc., which suggests special study as to its indications of deficient elimination.

The two special conditions of morning tire and anæsthesia of the sense of fatigue have been described as of the highest diagnostic value in respect to the neurasthenic condition. They do not afford differential indications, however, except that these symptoms are usually more pronounced in melancholia. It should be noted that morning tire is common as a transient symptom after excesses in dissipation or in over-work, but it becomes significant in neurasthenia by its more or less persistent recurrence.

Hypochondria may be differentiated as being subject to the principles just stated in so far as that it is a milder, or a sub-acute, melancholia, in which the patient has peculiar worries over his own bodily ills.

Insistent or fixed ideas may or may not be diagnostic of neurasthenia. They are common in melancholia, mania, etc., in the genesis of delusions, and may continue as sequels of such mental storms through the effects of mental habit and association of ideas, etc. While they are more likely to occur in neurasthenia, and thus become a symptom of it, they are sometimes initiated in persons constitutionally sound, and become the cause of neurasthenia by the worry that may attend them. They may directly initiate it, in fact, as a neurasthenic weakening of inhibition, and in some limited disorder of physiological processes as an association psycho-neurosis. The correct diagnosis of ideational disorders is important and valuable as affording indications for prognosis and treatment. Hysteria as allied to these affections often has a neurasthenic basis and appears as a complication; and it is peculiarly characterized by the anæsthesia of the special sense.

**Treatment.** — The diagnosis of the neurasthenic con-

dition having been made, upon physical and mental examination that for special reasons should be thorough in all particulars, the plan of treatment should be carefully laid out. The objective indications will be first considered.

*Elimination* of waste products is logically a prime element of the treatment. Not only should the alimentary canal be regularly and thoroughly evacuated, and the work of the kidneys be efficient, but the removal of the accumulations of toxic materials stored up in the tissues should be aided. Constipation from intestinal atony, as a frequent symptom of neurasthenia, will itself directly cause nervous irritability, depression, etc., and the functions of the various organs will be generally impaired. This demands a proper regulation of the bowels; and all means should be tried before regularly resorting to laxatives,—but they must be used if needed. The milder ones, like compound licorice powder, may be used at first, or the compound rhubarb or cathartic pills. But a cholagogue purgative has often an excellent effect,—one-sixth grain doses of calomel, every hour or half hour,—or five grains of gray powder every hour until action occurs,—or a few doses thus given followed by a saline laxative. A glass of cold or hot water, with perhaps some saline like Carlsbad salts, may be taken at bedtime or in the morning; the hot water especially has a washing-out effect upon the upper part of the intestinal tract, and acts as a solvent upon the contents of the intestines. Brunton<sup>68</sup> says that many cases of nervous irritability, depression and weakness appear like neurasthenia and hypochondria. Nerve tonics, sedatives, etc., are not needed; but for good results you must treat the bowels. Massage of the abdomen is useful, and small enemata of plain warm water, the rule being observed to solicit action at a certain hour every day. Fruit should be taken freely, and a good proportion of solid food when possible. Minute doses of aloin and strychnia, or one-tenth of a grain of aloin alone, or one or two grains of extract of cascara sagrada,<sup>69</sup> regularly after each meal, have a gentle and excellent effect; the morning doses and later those at noon, may be omitted as the patient improves. But the practical rule must be to give what suits the patient in each case.

*Elimination* by the kidneys is of the first importance. In cases of neurasthenia it is commonly found that the patients drink too little water, which is the best diluent and diuretic. Prescribe pure spring or distilled waters, which may be aerated,—not too much at meals, but between them or half an hour before; this should be done particularly when the urine is scanty and of high specific gravity. As Brunton says, it “tends to wash away the waste products from the cells of which our organs are composed, to clear out the uric acid, urea, and phosphates through our kidneys, and thus prevent renal and vesical calculi, and also to wash out our liver and prevent gall-stones, while it helps to keep the bowels in action.” In prescribing the daily consumption of hot water, a slice of lemon in it may overcome the dislike of it. A part of the beneficial effect of milk is doubtless due to increased ingestion of the water it contains, and milk and lime water, or soda-water, may be given to the same effect. Skim milk and whey are good diluents, and best suit some conditions of digestion.

Brunton regards the views of Haig, as to the elimination of uric acid, as an important contribution to our knowledge of the subject. These views have already been quoted, to the effect that the production of an excess of uric acid in the body is due to its deficient elimination in the urine; Haig says also that “it may be looked upon as going on to some extent in every one during the best years of nutrition and bodily activity,” tending to its accumulation in the tissues. Uric acidemia is therefore regarded by him and others as a condition that may ordinarily occur apart from the gouty diathesis, and be a source of much nervous disorder, including the feelings of depression, heaviness, drowsiness after meals, disinclination for bodily and mental exertion, sleeplessness, etc., which are the symptoms common to neurasthenia. The periodical attacks of headache, mental depression, etc., are thus accounted for in young people whose storage is less of uric acid, and the indication for treatment is a change from nitrogenous to farinaceous food. The persistence of these mental symptoms in older people indicates the probable need of clearing out the accumulation of uric acid in the tissues, spleen, liver, etc. The taking of alkalis according to the plan of treatment recommended, and the disorders of nutrition, etc., that increase the alkalinity of the blood, make it a solvent of the stored uric acid; this will cause acidemia, with a relatively slow, high-tension pulse, and the usually accompanying symptoms. It is greatest after meals and in the morning hours before and after breakfast, during the “alkaline tide” of the blood. Coincident with this is the “morning tire,” as has been stated. But if acids are given, wines or condiments containing them, or opium and other drugs that act like them,—as *nux vomica*, iron, nitro-glycerine, nitrite of amyl,—the uric acid is driven out of the blood into the tissues, relaxing arterioles by reducing tension, and improving the circulation. Mercury, by a like action, reduces the excretion of uric acid in urine, producing diuresis. All this is to the temporary relief of the disturbing symptoms, but it is not elimination and they tend to return in a worse degree. If there are exacerbations of headache, with nausea, etc.,—for example, a “bilious attack,”—give aromatic spirits of ammonia or *nux vomica* in place of acids; or, when acids fail, opium or mercury in small doses will sometimes succeed in affording the temporary relief then essential. Elimination is probably best effected by a course of salicylate of soda, with an acid mixture in alternate doses for weeks or months, till the daily excretion of uric acid remains for some time at the level of normal formation (1–33) as to urea; at the same time there should be as little of nitrogenous food as is compatible with healthy nutrition. The effect is to remove the cause of the irritative vascular disturbance. Then dieting is the main reliance, to limit the formation and retention of uric acid. Haig recognized the fact that when the nervous system is depressed by fatigue, deficient food, etc., disturbance of function will be produced by a smaller amount of uric acid in the blood than at other times. It is significant that these symptoms, common to neurasthenia and melancholia, are often observed in the latter to be ameliorated along with the return of normal excretion by the kidneys. Reference has been made to Brunton’s conjecture that oxaluria indicates the presence of some special poison in the blood. Cases with this symptom are commonly treated in the asylums with nitro-muriatic acid; Wood

<sup>68</sup> Lancet, June 20, 1891, p. 1365.

<sup>69</sup> This drug will be disappointing if it is not the product of the well-selected and matured plant, and reliably prepared.

reports some interesting cases of impending melancholia successfully treated in this way.<sup>60</sup> Such considerations give new interest to the physiological processes of elimination, and enlarge a special field for investigation into the causes and treatment of the nutritional disorders of neurasthenia.

The excretory action of the skin should receive attention, and it is promoted by bathing and bodily exercise. The neurasthenic do not bear cold bathing well, and its effect upon those who have previously used it to advantage should be observed. The effects of the warm bath should be noted while it is being taken, and afterwards, so that its temperature and duration may be regulated to suit the patient. Tepid and warm baths at night have a sedative and hypnotic effect also, and may be employed two or three times a week, oftener when well borne. The Turkish bath, when judiciously given, is useful in some such cases. The morning sponging with cool water, not more than 20° F. below the temperature of the skin, should be regularly practised. It should be given by the nurse until the patient is strong enough not to need assistance, — then the muscular effort is good in addition to the effect of the rubbing with a coarse towel, which should always follow the bath. At first the temperature of the water may be such as to give only a slight sense of coolness, and later it may gradually be made cooler. The patient should never feel cold or weak after the bath; the test of its being beneficial is the sense of warmth and comfort, or invigoration that it gives. The sitz bath and foot bath have their special indications. Sea-bathing on the northern New England coast is not beneficial to those who are much advanced in neurasthenia; in warmer waters it is often invigorating and useful, and should bear the test of the after-effects.

Menstrual irregularities are often neurasthenic and should be carefully observed and treated, though rarely by drugs. The douche may be used, when indicated, under ordinary rules. Suspension of the flow may be looked upon as conservative. An ordinary flow for the individual is often relatively too much, and should be limited. The patient usually has aggravation of nervous discomfort or severer symptoms at such times, and should be kept in bed from the beginning of the flow, or the day before, until one or more days after. Fluid extract of ergot has sometimes an excellent effect, in five to ten drop doses, three times daily, for two weeks before the event, or all the month. It regulates as well as diminishes the flow. Large hot douches, twice daily, when it is desired to arrest it after one or two days, have been employed with great advantage; two to four are usually sufficient.

(To be continued.)

THE EFFECT OF A MEDICAL LECTURE ON A CLERGYMAN. — At the recent meeting of the New Hampshire Medical Society, Dr. C. P. Frost related an anecdote illustrating the interest developed by Dr. Smith in his lectures on chemistry. In 1810, President Wheelock came from Dr. Smith's lecture-room to evening prayers in the chapel, and in his prayer gave thanks substantially as follows: "O Lord, we thank Thee for the oxygen gas; we thank Thee for the hydrogen gas, and for all the gases. We thank Thee for the cerebrum; we thank Thee for the cerebellum, and for the medulla oblongata."

### PERSONAL OBSERVATIONS ON THE PATHOLOGY AND TREATMENT OF NEURALGIAS OF THE FIFTH PAIR.<sup>1</sup>

BY JAMES J. PUTNAM, M.D.

(Concluded from No. 7, page 160.)

In one or two cases the intima of the blood-vessels was greatly thickened and the lumen of the vessel encroached upon and even obliterated by a dense tissue containing fibres and nuclei. In one or more large vessels affected in this way, the central mass of tissue appeared to be attached to one portion of the vessel wall, and opposite this the fenestrated membrane, everywhere else perfectly distinct, had entirely disappeared (Fig. 6).

FIG. 6.

Obliterated artery from the connective tissue surrounding the nerve and forming its sheath. A, external limit of artery. B, muscular coat, evidently altered. C, fenestrated membrane. The mass forming the centre of the artery is fibrillated, and contains a number of nuclei, and is continuous with the remaining coats of the artery where the fenestrated membrane seems broken through, and also at other points. Other arteries in the neighborhood of this one, all of them of large size, are in a similar condition.

In two of the nerves the axis cylinder and nerve tubes seem to have undergone various degenerated changes, such as swelling, displacement and destruction (Figs. 4 and 5). The examination of osmic acid preparations of teased fibres leads me to think that these appearances may have been due in part to the rough handling of the nerve during removal, but this certainly could not account for the whole of these parenchymatous changes. All the nerves were removed with a good deal of violence, and yet in most of them these highly marked changes in the nerve tubes were absent.<sup>10</sup> When they were present, on the other hand, their morbid origin was indicated by various collateral signs. Thus, there was a high degree of infiltration of nuclei among the nerve tubes; the axis cylinders had not only been displaced (as by pressure), but were wanting throughout the greater part of whole nerve bundles; while side by side with the immensely distended and altered fibres were others of normal size and structure, and sometimes again others of very small size suggesting newly formed (regenerated) fibres (see Fig. 1).

<sup>1</sup> Read before the Boston Society for Medical Improvement, March 23, 1891.

<sup>10</sup> At the time this paper was read I had not seen Dr. Dana's Medical Record, May, 1891, in which he says that he did not find much evidence of parenchymatous change.

It is very striking that apparently normal and diseased portions of nerve may lie side by side, that is, so far as the nerve elements themselves are concerned. In one entire fasciculus or portion of a fasciculus, there may be only a few normal looking axis cylinders, or perhaps not one, but only nerve sheaths containing myeline with or without the remains of displaced, swelled or shrunken axis cylinders, while other parts of the fasciculus, or other fasciculi of the same nerve, appear relatively unaffected.

FIG. 4.

[Drawn on smaller scale than the rest.]

Nerve-tubes of larger (A) and smaller (C) size, giving to the section a strikingly mottled look. The large tubes are of several times the normal diameter, and are filled only with granular myaline, sometimes with and sometimes without the remains of altered axis cylinders. The small tubes are apparently perfect in structure, but are smaller than the usual size, and may possibly be newly-formed fibres. Between the nerve-tubes are large numbers of nuclei (B). It is possible that these very striking changes in the nerve-tubes are in part mechanical, but this is not probable. The only mechanical violence used was in removing the nerve; but the absence of signs of pressure is against this; and the presence of the numerous nuclei indicates that inflammatory or degenerative changes have probably occurred.

FIG. 5.

Enlarged view of a portion of No. 4. A, normal nerve fibres. B, altered nerve-fibres. Numerous nuclei occupy the space between the fibres.

In some of the specimens small nerve bundles are to be seen running in the very midst of the perineural sheath, near its peripheral border, and the fibres in these bundles are often few in number and separated by thick trabeculae (Fig. 3). Sometimes no fibres remain. Whether it is proper to look on these bundles as representing the so-called *nervi nervorum*, which different observers claim to have made out, I do not know, but it is obvious that they are in a position to be painfully compressed by the thickened fibrous tissue of the sheath. In a specimen under the microscope (Fig. 3), a small artery is to be seen lying so close to one of these small bundles that one can easily imagine its pulsations to have been painfully felt. The sheath of this nerve contained an unusual number of small and large arteries and of these small nerve bundles.

The cells found lying in large numbers among the nerve fibres and in the sheath were of several sorts, principally: (a) long slender nuclei, parallel with the nerve; (b) round and ovoid cells of somewhat different sizes. I looked in vain in one or two of the nerves for cells with the characteristic staining of the so-called Mast-cells. The pieces at my disposal were usually small, and it is possible that my sections do not strictly represent the condition of all parts of the nerves.<sup>11</sup>

FIG. 3.

Portion of external sheath, showing the relation of small nerve-bundles (A) to the blood-vessels (B, see text). Many of the fibres of the nerve-bundle seem to have been destroyed, and their place taken by connective tissue. The blood-vessels were unusually numerous, and in some of them the intima was much thickened, and even the lumen obliterated by organized tissue.

A few words as to my own experience in the treatment of these neuralgias, and the lessons which the surgical cases seem to me to teach. I shall reverse the usual custom and begin with the surgical aspect of the subject, because resection or other operations seem to me the treatment to which, in a chronic case, we ought to turn first, instead of last, as is commonly taught. Successful as other modes of treatment often are, and true as it is that the persistence of a peripheral neuritis is no necessary bar even to the spontaneous cessation of the neuralgia for a longer or shorter time, and that operations sometimes fail to alleviate or alleviate only for a time, yet it is equally true that in a severe and chronic case no treatment can be counted on so confidently as a suitable operation, either to procure relief from pain or to secure the conditions favorable for rapid restoration of the nervous tone and nutritive condition of the patient.

Unless there are strong arguments against an operation, why should we advise the patient to pursue the longer and more painful road to recovery to which

<sup>11</sup> The drawings were made with the camera lucida by Dr. Abbott and Mr. Philip Wynne.

tonics and anodynes point the dubious way? No one has heard the expressions of gratitude of a patient after successful operation, or seen flesh and color return, but he would be glad to hear and see them again.

Is the operation, in skilful hands, really a very serious one?

During the past five years sixteen patients have been operated on at the Massachusetts General Hospital twenty-six times, and at several of the operations two or three nerves have been removed.<sup>12</sup> All of the patients received a considerable measure of relief (see Appendix), and the only untoward results recorded or known to me were that two patients had suppuration of the jaw for a short time, and one, after section of the inferior dental nerve within the mouth, by the Paravincini method, had a curious impairment of the use of the tongue, causing a marked lisp, which, at the end of several years, has not fully passed away.

If the private records of the hospital surgeons were added to this list, the showing would be much improved, and it would, I think, be admitted that an inflamed nerve is usually to be regarded as a thing to be got rid of almost as much as if it were a foreign body; but, as every one knows, a thorough operation often gives a long period of relief when there is good reason to believe that no severe primary neuritis was present, or when the whole of the inflamed part could not be removed, or when more than one branch was involved, but only one removed.

Dr. George R. Fowler, of Brooklyn, in an interesting paper published in the *Annals of Surgery* for 1886, gives a record of eighty-three cases of neurectomy. One patient had slight facial paralysis; one who left the hospital in cold and damp weather, without permission, on the seventh day, free from his neuralgia, but not free from his stitches, died of tetanus; the rest, so far as the operation was concerned, did well. A number of cases of ligation of the carotid did not make so favorable a showing, as one might readily anticipate.

It should be said, in addition, that several of the patients operated on by the surgeons of the Massachusetts General Hospital were in advanced life, and that several of the operations were for removal of the nerves close to the skull.

What indications can we find that can aid us as to the character of the operation?

I have indicated my belief that in most cases of neuralgia two elements are usually present in varying degrees, an irritable condition of the nerve-centres, and some one or more peripheral irritations. To overcome the first of these conditions, it is probably important to cut off, so far as possible, the stream of impulses that fall upon the diseased nerve-centre, whether these come by way of nerves that are themselves inflamed or by way of (contiguous) healthy nerves. I think the operations should, therefore, be both extensive and deep; extensive, so as to include as large a peripheral area as possible, the probability being that it is useful to cut off even the normal peripheral areas that are especially related to the diseased nerve-centre; and deep, in order to get rid of as much as possible of the diseased nerve and its thickened sheath.

<sup>12</sup> Since this paper was first written a number of successful operations at the foramen rotundum and foramen ovale have been made by Drs. Richardson, Mixer and Cabot, and the belief has gained ground that this radical method is really the best.

I have already called attention to the important part probably played by the circulation in the inflamed nerve as a cause of irritation of the nerve bundles ramifying in the sheath. The sheath of the inflamed nerve forms, in fact, an important peripheral area. I will, however, repeat that the irritability of the diseased centre is, after all, probably the essential thing. If this were not so, it is hardly probable that the pain would return with such violence after the regeneration of the cut nerves.

I should be glad if the time and my knowledge allowed me to speak critically of the different operations that have been recommended. I hope, however, that these points will be brought out fully in the discussions. I will only say, that, as the operations in general have come more into favor, and as neurectomy and nerve-stretching have displaced neurotomy, so the deep operations have been, of late, displacing the more superficial operations. It is probable that forcible stretching, or even avulsion, adds something of value to neurectomy, though it introduces an element of slight danger which has been pointed out by Lagrange (case of ulceration of the cornea from avulsion of the infraorbital; no reference given).

An English surgeon, Rose,<sup>13</sup> has recently trephined the skull, and broken up the Gasserian ganglion for neuralgia. The patient had inflammation of the cornea, and lost the eye, but the writer thinks this could be prevented another time.

I did not intend, in speaking highly of operative treatment, to undervalue the other measures, which often surprise us by their action. I cannot enumerate them at length, but must acknowledge my indebtedness to a few.

Prominent among these is aconitia,<sup>14</sup> in full doses first recommended I believe, by Gabler; then, the rest and "overfeeding" cure, carried out with sufficient thoroughness to secure an increase in flesh and color. Galvanism is often an invaluable adjuvant.

Two sets of cases have also been reported that have interested me very much. One set, comprising thirty-three cases, collected by Gussenbauer and Pietrzikowski, of Prague,<sup>15</sup> are stated to have been all cured by thorough, mechanical hygienic, and medical treatment of chronic constipation. These observations may at least contain a useful therapeutic hint. In another set of cases, Leslie<sup>16</sup> obtained excellent results from the insufflations of common salt into the nostrils, repeated each half minute for five minutes; and in this connection I would refer to the occasional value of cocaine instilled into the eye in supraorbital neuralgia.

It should never be forgotten, when we are trying to estimate the value of any therapeutic measure, that the pain, even in these severe forms of neuralgia, is liable to remit suddenly, even without treatment, and remain away for a considerable period, in spite of the persistence of neuritis or other causes, and this too even with elderly people, as I have several times witnessed. Any remedy, now, which breaks in on the neuralgic habit is liable to bring about one of these remissions, and although the pain may disappoint the

patient by returning, yet a valuable interval may be gained. Thus, in a favorable case, a few large doses of aconitia may cut short an attack for days or weeks. The "inhibitory" effect of various operations about the face is to be reckoned in the same category; and likewise that of sudden nervous shock; and, last—but not least in importance, because more often available—that from hypnotism. I have not actually used this latter treatment myself, but a number of successful cases are on record.<sup>17</sup>

As an instance of the action of mental shock, the case of Sir John Lawrence may be cited. He had suffered excessively for a long time from facial neuralgia, and was still suffering, when the news of the Indian mutiny was brought to him, with its intense anxieties and calls for unremitting labor. At once the neuralgia disappeared, not to return.

At the time this paper was first written I had not seen Dr. C. L. Dana's article in the *Medical News* of May 16th, in which he describes the changes in some nerves examined by him. Although my observations and those of Schweinitz do not wholly agree with his as to the absence of changes in the nerve-tubes themselves, yet I concur with him in thinking that it is the irritation, not the destruction of the nerve, which causes the pain. With regard to the point which he makes that the absence of anesthesia is an argument against any considerable degree of nerve degeneration, I cannot concur. The evidence is very strong that so long as a nerve is not wholly destroyed the sensibility of the skin which it supplies may remain normal, for ordinary tests at least, and also that contiguous nerves may do duty for each other.

#### APPENDIX.

I have, unfortunately, not been able to get late news of the majority of the patients operated on at the hospital, even by correspondence. Such facts as I have are as follows: All were well, or practically well, at the time of their discharge. The pain is not known to have returned in any case where the nerves were cut at the foramen, but the information only covers periods of from a few months to two years. Of the other cases, one patient is still free from pain after four years; one after two years and a half; one after two years. In two cases the pain is known to have returned, as so often happens, but after a long interval of relief; and, of course, in the cases where more than one operation was performed the pain had returned in the interval.

#### SMALL SUB-SEROUS FIBROIDS OF UTERUS THE OCCASION OF GREAT INTOLERANCE OF THE BLADDER.<sup>1</sup>

##### A CASE: OPERATION, RECOVERY.

BY W. H. BAKER, M.D., BOSTON.

THE following case is of interest as showing

(1) The importance of verifying the position of the uterus when determined bimanually, by the passage of the uterine probe.

(2) The necessity of examining, under ether, in a case when the diagnosis is doubtful, or difficult of

differentiation, on account of thick or rigid abdominal walls or from the extreme sensitiveness of the pelvic organs.

Miss M. C., thirty-five years of age, a native of New Hampshire, consulted me first May 24, 1890, and gave the following history: Menstruation was established at fourteen years of age, occurring regularly afterwards until four or five years ago, when it began to anticipate the time by three or four days. Dysmenorrhœa was present only each second or third month, but at such times of pain she was obliged to go to bed. The time of each period was four days, and the amount twelve saturated napkins. She generally felt miserably for a week after the flow had ceased. She had had no serious sicknesses during the course of her life. She became run down about five years ago; felt badly all over, as she expressed it. At that time she first consulted a physician, and had been under treatment most of the time since. From leading an active life and exercising much in the open air, riding horseback and walking, she gradually became more and more of an invalid. The suffering, which was greatly intensified by any exercise, consisted of very frequent desire to urinate. There was no dysuria, but the greatest intolerance of the bladder to holding more than a very small amount of urine. This was most troublesome during the day-time when she tried to be on her feet, but was not altogether absent when lying down or when sleeping at night, as she would be awakened four or more times by the distress in the bladder, which was only relieved by urinating. She was practically debarred from engaging in any employment, and had settled down to a quiet semi-invalid life at home. Added to this suffering was a sense of weight in the pelvis, and oftentimes distress in the rectum when in the erect position. Previous treatment had principally been the use of the hot vaginal douche and the support of the uterus by a vaginal pessary. For a period of two years after the pessary was first adjusted she felt much better, all the symptoms being greatly alleviated. After that period of time, however, all her former suffering returned; and although she continued the use of the pessary, she felt that it was an insufficient support, and constantly desired that it be changed, entertaining the hope that thereby she might derive the relief she had previously obtained by such instrument. Finally, the large size of pessary which had been applied caused so much vaginal irritation that she removed it, and consulted me as previously indicated.

On making a vaginal examination, I found that canal much irritated, and on either side near the outlet a small ulcerated surface where the sides of the pessary had imbedded itself. In one month, when I saw her again, by the use of the hot vaginal douche and rest, the vagina had quite recovered itself, and I was able to examine her more thoroughly. Both digitally and bimanually the uterus felt to be in a position of extreme antelexion of body and neck; but so sensitive was the whole organ, that, although I made a prolonged attempt to pass the uterine probe, I failed utterly in entering the uterine cavity with that instrument, and was obliged to content myself with the bimanual examination, which I was loath to do, inasmuch as the abdominal walls were thick and rigid, allowing only an imperfect palpation of the pelvic inlet. A "Graily-Hewitt" soft-rubber, anteversion pessary was adjusted, which was well tolerated by the vagina, but which gave her only partial relief from

the intolerance of the bladder. Analysis of the urine showed nothing abnormal.

During my absence in the summer, Dr. Burrage substituted a hard-rubber pessary of the same pattern, which gave her more relief for a time, but in November she presented herself again, suffering from all the former symptoms in a greatly increased degree. I felt that we could no longer be satisfied with the imperfect examination previously made, and suspected from the long continuance of the sensitiveness of what seemed to be the body of the uterus, that it might prove to be an adventitious growth.

On November 18th, an examination being made by the aid of ether, I found the uterus retro-curved with ante-flexion of the cervix, and elongated to an internal depth of three inches, apparently held in its backward position by a body in front and slightly to the left of the uterus. This mass was indistinctly movable from the uterus, being about the size of a hen's egg and of somewhat irregular surface. It was thought to be either an ovary or a pedunculated out-growth of the uterus. The uterus was not freely movable, and the tubes and the ovaries could not be otherwise distinguished.

I advised the operation of celiotomy, and removal of the growth, at the same time breaking up any adhesions which might be holding the uterus in its malposition, and, if, necessary, stitching the fundus to the abdominal parietes.

January 21, 1891, assisted by Drs. Burrage and Pratt, I operated through an incision in the median line, half way between the umbilicus and pubes, two inches in length, which was subsequently enlarged to three and one-fourth inches. With two fingers in the abdominal cavity both ovaries and tubes were felt to be normal. A growth, apparently a fibroid, was found springing from the anterior surface, and slightly to the left side of the uterus, and quite down to the lower part of the body of that organ. Its pedicle was thick and vascular, perhaps one and one-fourth inches in length and one-half an inch in thickness. The omentum was firmly adherent to the anterior surface of the fibroid. This was with some difficulty peeled off. The pedicle, included in a Spencer-Wells obtuse angled forceps, was ligated with stout braided silk. In tying the ligature about one-third of the pedicle was cut through, and a considerable hæmorrhage ensued; it was controlled by sewing the pedicle through and through with the suture, which was now quite down on the uterine tissue; subsequently the pedicle was sewed over and over with a whip stitch. No adhesions were found about the uterus, and the necessity for stitching the uterus forward was not apparent. The abdominal cavity having been washed out with warm water, the abdominal wound was closed with interrupted silver sutures, and the wound dressed with iodoform, collodion, gauze and strapping.

Patient was put to bed in good condition, and her recovery was uneventful. She was able to sit up in two and one-half weeks from the date of the operation, to walk about in three weeks, and was discharged from the hospital in four weeks.

In this case temporary relief was obtained by the use of vaginal supports, it is true; but as the tumor grew, they became inefficient, and her life was made increasingly intolerable by the growing irritability of the bladder. Just what was the nature of the growth in front of the uterus it was impossible to say until the

intraperitoneal examination was made; then it at once became evident that, in order to give any permanent relief, entire removal of the fibroid must be accomplished.

The success of the operation is shown in that she now complains of none of her former inconveniences. The desire for urination occurring only three or four times in the twenty-four hours; neither is her rest broken at night as formerly by the desire to empty the bladder. The uterus has resumed its normal position in the pelvis.

I have been led to report this case in full inasmuch as in my experience it is rather exceptional that a small fibroid produces such an intolerance of the bladder or in fact of any of the surrounding organs. Usually their growth is so slow that the surrounding organs became accustomed to their presence, and it is more from their weight, together with the displacements of the uterus and its consequent engorgement thereby induced, that the patient suffers. Reference in this connection is more especially made to subserous fibroids. Much more frequently do we see symptoms of a reflex character, arising from small fibroids of the subserous or even interstitial variety.

## Clinical Department.

### CASE OF ACUTE PLEURISY WITH LARGE AMOUNT OF EFFUSION.

BY ARTHUR P. FERRY, M.D., JAMAICA PLAIN.

JOHN C., laborer, age twenty-seven years, sent for me on the evening of April 8th last, to relieve a slight cough and difficult breathing, which he had had about ten days. He had worked, as the weather permitted, until five days before my visit, and the day previous had been seen by a physician, who told him he had a cold only and would soon be well.

Patient weighs about 165 pounds; height five feet, ten inches; chest measurement (as taken afterwards) thirty-eight inches, after a full inspiration; pulse 100, rather weak; temperature 100°; respiration 32, labored.

Percussion showed dulness over the upper portion and flatness below the level of the fourth rib on the left side. The resonance over the right chest was increased. On auscultation no respiratory sounds whatever were heard on the left side, and there was almost a total absence of heart sounds, with no impulse. In the right chest the respiratory sounds were increased in volume, and the heart could be heard beating feebly between the right nipple and the sternum.

As all the symptoms indicated an effusion into the pleural cavity, I told him my diagnosis, and proposed aspiration, but not having an aspirator with me, was obliged to wait until the next morning.

The amount of fluid drawn filled the bottle four times, and by actual measurement amounted to 129 fluid ounces. The patient felt a little faint during the early part of the operation, but at the end was so far recovered as to ask if he could go out-doors that day. The next day the heart was found to have returned to nearly its normal position, and the lung had expanded considerably.

About the first of May the patient, by request, visited me in my office. Some fluid had accumulated

since the last examination on April 10th; but he declared he felt well, and was working every day.

Several gentlemen have assured me that this is the largest amount of fluid removed from the pleural cavity at one aspiration of which they have ever heard.

## Medical Progress.

### REPORT ON DERMATOLOGY.

BY JOHN T. BOWEN, M.D.

#### ACTINOMYCOSIS OF THE SKIN.

SINCE Israel, in 1878, established the existence of a parasitic disease in man, that was proved soon after by Ponfick to be identical with the actinomycosis described by Bollinger in cattle, a considerable number of instances of this affection have been reported where the skin was attacked, either alone, or in conjunction with the internal organs. Ponfick has asserted that any portion of the outer integument and of the mucous membrane may afford entrance to the parasite, provided an open door is offered by a loss of tissue. The most frequent seat of the cutaneous affection is the region of the face and jaw, a carious tooth having in many instances proved to be the starting point of infection. No very characteristic clinical appearances are found as a rule, but chronic suppurative processes, with nodules and infiltration of the dermal tissue, serve to suggest the possibility of this affection. The source of infection in cattle is doubtless very frequently to be found in the feed, as Johnne and Ponfick have discovered vegetable fibres and grains of corn covered with the characteristic actinomycosis parasites, in the jaws of healthy swine. In man, also, the probabilities point to the view that vegetable matter is the carrier of the parasite, as nearly one-half of the cases have shown primary lesions and fistulae of the mouth and throat, although the possibility that many of the cases of pulmonary and intestinal disease are due respectively to a direct aspiration and swallowing of the parasite, should not be overlooked. Many of the cases of cutaneous actinomycosis have been shown by operation to be connected with lesions of the internal organs, as the lung and intestine, by fistulae caused by the outward progress of the disease, yet undoubted instances of the skin's being attacked primarily are on record.

Thus Müller<sup>1</sup> relates the case of a man who had received a splinter in his forefinger, which remaining had been covered in by granulations. Two years later an infiltration occurred at this point, and on examination the parasite of actinomycosis was discovered in the new growth. There is a general belief that the disease in man differs from that in cattle, solely in the addition of a septic process. In cattle a pure granulation tumor alone is present, while in man, besides the granulation tissue, the evidences of suppuration are so marked and constant, that we are forced to regard it as a mixed affection—actinomycosis plus sepsis.

A case of actinomycosis of the face is reported by M. M. Darier and Gautier in the *Annales de Dermatologie et de Syphiligraphie*, for June of this year, which offers, indeed, no new light, but is interesting on account of the small number of cases reported

outside of Germany, and which will further serve as a good example of the affection.

A female, twenty-five years of age, a native of Prussia, but an inhabitant of Paris for seven years, where she was employed as a cook, had her first symptoms nine months previously, when she noticed a small subcutaneous nodule in her right cheek, which increased slowly in size, finally involved the cutis, and opened spontaneously, giving exit to a small quantity of pus. Soon afterward other smaller nodules appeared around the part first affected, many of which were opened by incision, or broke, emitting a small amount of pus or blood. The patient was admitted to the Hôpital St. Louis, where the following condition was noted. The whole of the right cheek occupied by a violet red patch, covered in some places with large scales, not raised as a whole, but presenting a half dozen hemispherical elevations, of the diameter of a centimeter, some of them ulcerated at the tip and covered with small crusts. These elevated nodules were found to be soft and fluctuating, and to be seated upon a hard base, which exceeded the limits of the red plaque even, and which was manifestly adherent to the superior maxillary bone. The lower eyelid was the seat of a soft oedematous infiltration. The lesions were somewhat painful, but the patient's general health was excellent. The small tumors were incised, and in the pus obtained, small yellowish-white granules could, with difficulty, be distinguished by the naked eye, which on microscopic examination proved to be the nodules of actinomycosis. They were well seen by simply spreading the pus in a thin layer on a slide, or by adding a little salt solution. Each drop of pus contained about a dozen of the nodules. Of etiological importance in this case may be the fact that nine months previously this patient had had an alveolar abscess of the second upper incisor of the right side, which was the seat of a considerable caries.

The treatment instituted in this case may seem somewhat novel. It was according to the method of M. Gautier, by which a solution of iodide of potash injected into the tumors was decomposed by a current of electricity. Two platinum needles were inserted into the tissues and every two minutes during the operation several drops of the iodide of potash was injected. This treatment proved successful after a good many repetitions, and at last accounts there remained no traces of the lesions beyond a redness with some cicatrization.

#### DESTRUCTION OF HAIR BY ELECTROLYSIS IN FRANCE.

The destruction of hair by electrolysis was, as is well-known, introduced by Dr. Hardaway, of St. Louis, and remained for some time a distinctly American practice, foreign dermatologists showing little tendency to seriously undertake the operation. That its adoption is becoming now more universal is illustrated by several papers from the pen of Dr. Brocq, the well-known dermatologist of the St. Louis hospital in Paris. Brocq follows essentially in his methods the procedures adopted in this country, but a review of certain points in his writing may prove interesting, even if not acquiesced in by the American of experience.

Brocq uses a battery of twenty-four cells and a finely adjusted galvanometer. His needle is of iridoplatinum and bent at an angle, in order to serve as a guide to the depth which the point has reached, and to facilitate the operation upon parts of the face not

<sup>1</sup> Beitrüge zur Klin. Chirurgie, Bd. III, Hft. 3, p. 355, 1886.

easy to reach. When the needle has been inserted into the follicle, the patient holds the electrode connected with the positive pole in his hand, while an assistant regulates the current until the galvanometer records the required strength. If there is no assistant, the patient must take care not to complete the circuit until the needle is in place, on account of the pain produced by the repeated attempts that may be necessary before the needle is successfully inserted. Brocq considers that the use of cocaine in ointments and lotions has not very much effect in diminishing the pain. He often uses the following ointment, however,

Hydrochlorate of cocaine . . . . .	.50
Lanolin . . . . .	5.
Vaseline . . . . .	4.
Extract of violet . . . . .	q. s.

which is rubbed into the part that is to be operated on at three different times, a half hour and a quarter hour before the sitting and at the moment of beginning. The pain he thinks is, by this means, somewhat lessened. The current used is from two to three milliamperes for hair that is very fine, or when very sensitive or conspicuous portions of the face are being treated. For medium sized or very stout hairs four to five milliamperes may be reached. With regard to the time that the current is allowed to pass, the operator must be the judge, as the necessary skill can be acquired by experience alone. Brocq recommends using a considerable amount of traction with the forceps on hairs situated in conspicuous places. In this way there will be a larger number of recurrences, but one will approach nearer to the exact moment when the bulb is destroyed and there will be no danger of leaving scars. He also advises to wait a few moments and then repeat the traction with the forceps, in case the hair does not come readily at the first trial. As to marks left by the operation, Brocq says they vary according to the numbers and quality of the hairs, according to the individual, the part treated, and the fineness and quality of the integument. One patient will have no trace remaining after five or six days; another will show for several weeks a brown pigmentation, or red points becoming white when the skin is stretched. These last are all that is seen when medium sized hairs are removed. When very stout hairs are treated, for which it is necessary to continue the current for a long time, certain predisposed individuals may exhibit small cicatricial indurations of the size of a pin's head, scarcely or not at all visible, but perceptible to the touch. Often small circular depressions are seen which tend to disappear spontaneously. Brocq regards vaseline, glycerine and cold cream as substances tending to stimulate and increase the growth of the downy hairs, and recommends his patients to content themselves after the operation with a simple starch powder.

He questions whether it would not be better, when a fine growth is appearing on the face of young women, to destroy it before time and repeated epilations have rendered the hairs coarse and thick and much more difficult to treat.

[Probably in no other operative procedure is it more difficult to lay down precise rules than in electrolysis for removing hair. The experience of the operator is of importance, a considerable apprenticeship being absolutely requisite for success. Different operators may accomplish equally good results by following methods quite dissimilar in their minor details. Thus an experienced operator can do the very best work

without the aid of a galvanometer, while the beginner needs all possible instruments of precision for his assistance. Little that can be written as to the number of hairs removed at a sitting, is of value. No number should be allotted to a given time, as it depends upon the character of the growth, the irritability of the patient's skin, the courage of the patient, the quickness of the operator, etc. The current of four to five milliamperes used by Brocq for the stouter hairs, while perhaps a safe one in experienced hands, should not be attempted by persons of inexperience. Very good work, with a moderate number of recurrences, may be done with one and one-half milliamperes, and the reporter's experience leads him to doubt if it is ever wise to exceed two milliamperes in cases where the best results are desired. Rep.]

#### "CABUL LEPROSY."

In an article in *La Tribune Médicale* for July, 1890, Dr. E. Verrier discusses the disease known as "Cabul leprosy," and its relation to syphilis. The article has been rendered into English by Dr. C. W. Cowles, of Hampstead, from whose translation we quote. It seems that in this disease there is a condition of enormous exostosis of the tibia and of the bones of the forearm, arm and face. Soft tumors, adherent to the bone and involving the cutaneous tissues are often found about the articulations of the elbow joint, and also upon the malar bone and the integuments of the cranium, and they are quite as apparent at the beginning of the disease as when it has become more generalized. When these tumors are situated in the skin or in the muscular tissue, they have, at first, an elastic consistency resembling that of a gumma. At a more advanced period the tumors break down and give exit to the products of necrosis of the tissues, including the bone. Around the margins of these ulcers the tissues are "sticky," of a gummatous consistency. On the forehead cicatrices are often noted, where these lesions have left their marks. There are also observed ulcerations of the nasal fossa, and of the roof of the mouth, the velum of the palate, and caries of the nasal bones. Cases of "Cabul leprosy" where these lesions are dominant, Dr. Verrier regards as nothing more nor less than syphilis. "Scrofula" he regards as sometimes complicating the syphilitic disease, and that it is this association that has contributed to the mistake of regarding the disease as true leprosy. Inasmuch as inoculable sores are rare in Cabul and as one-fourth of those afflicted with Cabul leprosy are infants, he considers hereditarily to play a chief rôle in the transmission of the disease.

#### "ICHTHYOL VARNISH."

Unna,<sup>2</sup> who has made extensive use of ichthyol in the form of ointments, pastes, ichthyol-collodion and ichthyol-gelatine, recognized the need of an ichthyol varnish that would not have the disadvantages of the collodion and gelatine in being somewhat irritating to an abraded skin, and that would not possess the hygroscopic qualities of the pure drug. He believes that a good many specialists have been less successful in the treatment of rosacea and lupus erythematosus with ichthyol, because they have used the drug in the form of ointments and pastes.

For this purpose he experimented with various substances and found that if starch were added to ichthyol the mixture was not hygroscopic, and that to this mix-

<sup>2</sup> Mummelshett, *Z. prakt. Derm.*, Bd. xlii, No. 2.

ture albumen must be added in order to keep the starch in suspension. The formula for this ichthyl varnish reads,

Ichthylol	. . . . .	40 parts.
Starch	. . . . .	40 parts.
Sol. albumen	. . . . .	1-1½ parts.
Water, ad.	. . . . .	100 parts.

The starch is first thoroughly mixed with the water, then the ichthylol added and lastly the solution of albumen. Another formula in which carbolie acid is incorporated is:

Ichthylol	. . . . .	25 parts.
Carbolie acid	. . . . .	2.5 parts.
Starch	. . . . .	50 parts.
Water	. . . . .	22.5 parts.

This varnish is intended especially as a dressing in minor surgery, as it dries quickly, and can easily be removed by water. The soluble ichthylol varnish combines all the advantages of the various ichthylol preparations without their disadvantages. It dries quickly and is not dissolved by the perspiration. It is valuable in acne in persons with a very sensitive skin, in rosacea, and in lupus erythematosus. In some forms of eczema and in erysipelas it is of great service.

This varnish is also made the vehicle for other drugs, on the principle that several therapeutic agents of the same class may, with advantage, be united in one prescription. In this way a more powerful effect may be produced, while the disadvantages of the several drugs are lessened. For example, two to five per cent. of chrysarobin may be added to the ichthylol varnish for use upon the face, and used with the same security as chrysarobin-collodion. Certain circumscribed forms of eczema, psoriasis and other affections may be treated by combining pyrogallol, resorcin and sulphur with the ichthylol varnish. It is to be noted that in order to obtain a suitable consistency, an amount of water or oil, equal to that of every new medicament added, should be mixed with the varnish. For this purpose linseed oil is used as a rule.

#### BULLOUS ERUPTION FROM ANTIPYRINE.\*

The subject, a man thirty-three years of age, had a history of numerous attacks of rheumatism. Immediately after taking some medicine prescribed by a physician for headache, he was seized with a violent itching of the palms, soles, lips and glans penis, which were soon covered with bullæ as large as a bean, and on palms and soles there also appeared urticarial patches that did not develop into bullæ. This attack, accompanied by slight fever and malaise, lasted four or five days. Four weeks later while suffering from influenza, a precisely similar eruption occurred after a dose of antipyrine, and the same results were observed after taking the same medicine twice during the two months following. Shortly after this he was seized with an acute inflammation of the knee-joint, for which one grain of antipyrine was given. Two hours later the bullous eruption appeared just as before, while the pain in the joint and the headache disappeared. The diagnosis of an antipyrine eruption being highly probable, it was determined to test the matter experimentally, and at 8 o'clock he was given one grain of antipyrine, followed by a half grain at 9 o'clock. At 9½ intense itching in the anal region, at 10, burning sensations of the palms and soles, and at 11, lips greatly reddened and swollen with marked reddening of the gums. Later there appeared erythematosus and urticarial

patches of palms and feet and upon the glans penis, and by evening the whole face was greatly swollen, conjunctivæ congested, temperature 39.2° C., constitutional disturbance marked. On the following day the lips were still greatly swollen, but the erythema of the face and conjunctival injection had nearly disappeared. Several bullæ as large as a pea were found upon the hard palate. The patches upon the hands, feet and penis remained, and had not entirely disappeared until the expiration of three weeks, and a copious desquamation of the affected portions followed the attack. The points of especial interest in this case are the constant localization of the eruption on lips, gums, hands, feet, and penis, and the concurrent rise of temperature.

#### PURPURA HÆMORRHAGICA.

Numerous attempts have been made of late years to discover the cause of purpura hæmorrhagica, starting with the assumption that we have here to do with a chronic infectious disease. The observations made have not reached a very satisfactory conclusion, however, although Letzerich was able to cultivate a bacillus from the blood of a girl suffering from this disease, which he inoculated upon animals with the result of producing a dilatation of the capillaries with hæmorrhagic spots and extravasations. Oddly enough Letzerich himself was taken ill with a tedious attack of purpura hæmorrhagica some three years after these experiments were made, and from his blood the same bacillus could be cultivated.

Kolb's<sup>4</sup> work was performed under the guidance of Dr. Petri, and five cases of purpura hæmorrhagica were obtained as material. Three of these cases belonged to the type described by Henoch as purpura fulminans, which ends fatally in from twenty-four hours to four days, while the remaining two were of the ordinary milder variety, the patients recovering in from two to three weeks.

[A more exact clinical description of these cases would have been valuable, in view of the probability that, under the term purpura, which is strictly speaking a symptom merely, we may include different pathological processes. Rep.]

In these five cases, specimens of blood were first taken from the living subject to determine if a specific agent could be detected by culture or inoculation—but only negative results were obtained. Three of the cases, however, ended fatally and the autopsy in each revealed copious hæmorrhages and extravasations throughout the internal organs. Pieces of the glands, liver, spleen, kidneys, and purpuric patches of the skin were excised, and exhibited in hardened sections a moderately large bacillus with rounded ends, situated chiefly in the vessels, although partly in the interstitial tissue. The fresh tissue served as material for cultivation, and also for experimental inoculation. A large number of animals (405 in all) were used in these experiments and it was proved that in almost all cases purpuric spots and general internal hæmorrhages could be produced, with the constant presence of the bacillus described. Inoculation of pure cultures of the micro-organism also gave quite constant results upon animals, guinea-pigs alone proving to be but slightly susceptible. The bacillus was somewhat similar in appearance, staining, and behavior in culture media, to seven

\* Viel: Naturforscherversammlung, Bremen, 1890.

<sup>4</sup> Arbeiten aus dem Kaiserlichen Gesundheits Amte, Bd. vii, Berlin, 1891.

other known varieties, yet distinct points of difference from each of these are pointed out. In order to determine whether the hemorrhages were dependent wholly upon the bacteria or whether the products of retrograde metamorphosis were not also causative, cultures in large amounts were sterilized and filtered, and inoculations made on animals. The result showed that these fluids also which were free from bacteria, could produce the characteristic hemorrhages in rabbits and mice, and pathologically the same appearances were revealed.

Kolb concludes that inasmuch as in three pure cases of purpura hemorrhagica the same bacillus was cultivated, which could produce in different species of animals, a pathological process similar to that in man; and as a bacillus identical with that found in the human body could be cultivated from these inoculated animals, the three requirements of Koch have been fulfilled, and that in these cases he had to do with an affection caused by the bacillus that he has described. He thinks that this bacillus, for which he proposes the name bacillus hemorrhagicus, will be found to be present in all cases of pure purpura hemorrhagica.

#### PATHOLOGY AND TREATMENT OF ALOPECIA AREATA.

Dr. H. Radcliffe Crocker,<sup>8</sup> reading before the British Medical Association on the above subject, reported an analysis of 207 cases of alopecia areata in 10,000 cases of skin disease, indicating a frequency of two per cent.; and of 50 cases occurring from a total of 1,500 in private practice, a proportion of 3.3 per cent. The number of males was slightly greater than that of the females. In hospital practice the greater number were under twenty, while in private practice the largest number were found to be between twenty and forty. Speaking generally, we may say that the disease is most common under twenty years, frequent between twenty and forty, uncommon after forty, and rare after fifty.

After speaking of the controversy between those who advocate the tropho-neurotic and parasitic theories respectively, he declares his position to be with the French, believing that there are both parasitic and non-parasitic cases of alopecia areata. Under the generic term alopecia areata, then, he describes four classes of cases.

CLASS I. Here he places those cases where the alopecia is universal, and in which the hair does not necessarily come out in patches. This form is often accompanied by changes in or falling off of the nails, and is apt to pursue a rapid course, and to be permanent. Many of these cases have succeeded worry, fright and injuries to the head.

CLASS II are cases of baldness occurring in one or more patches at the site of an injury or in the course of a recognized nerve.

CLASS III is the form originally described by Neumann as alopecia circumscripta seu orbicularis. Here the patches are circular and always small in diameter, from a lentil to a pea in diameter, much depressed below the surface, with often a marked decrease in the sensibility. It is a rare form, and the prognosis is unfavorable. The depression of the bald area below the surrounding skin, with the appearances of atrophy, is a marked feature of this form.

These three classes he regards as essentially of a tropho-neurotic character. Collectively they form

only a small proportion (five to ten per cent.) of cases classed as alopecia areata.

CLASS IV is not only the largest by far, but the one most open to discussion as to the origin of the affection, and the writer has come to the conclusion that it is due to a vegetable parasite. The cases occur chiefly in patches from one-half to two inches in diameter, primarily round, but often irregular from the confluence of several patches. They may occur on any part of the scalp, but more commonly on the occipital region. Short hairs about one eighth of an inch long, thicker at the free end than at the point of insertion, may be seen in the more recent cases. In 80 per cent. of Crocker's cases of this class, the health was perfectly good. If this were a neurosis, he considers it unparalleled that it should be (1) a very common disease. (2) Most common in the prime of life. (3) That four-fifths of those affected should be in perfect health otherwise. A large number of cases in the writer's personal experience are then related, where patches of alopecia areata occurred in adults who had been in close contact with cases of tinea trichophytia.

In children cases occur which it is impossible to distinguish from alopecia areata clinically, where a direct history of contagion from tinea trichophytia can be discovered. Crocker declares that he has repeatedly seen cases of typical ringworm of the head, which, after being treated for some time, change into smooth bald spots identical with those of alopecia areata, and that tinea tonsurans may present totally bald spots from the beginning. His conclusions are that tinea tonsurans and alopecia areata may be interchangeable in children, while in adults we see practically only one, the bald form, and the question is forced upon us, "Is not alopecia areata in the majority of cases not only non-neurotic, but parasitic, and is not the parasite that of tinea tonsurans?" This would account for the otherwise curious fact that while ringworm of the scalp is so common in children, it disappears after puberty. Crocker believes that the fungus can be demonstrated in recent cases if properly looked for—that it is not *in* the shaft, but *on* it, or on the attached epithelium, and he suggests the possibility that the hair alters in its consistence after puberty, so that the fungus cannot penetrate it. The best way, he thinks, is to pull out a good many of the loose hairs at the border of the area, then to examine them with a lens, and select those hairs which have most root sheath attached. These are soaked in liquor potassae, and the portions of epidermis attached to the shaft examined. The fungus is always in small foci, and perhaps in only one of several selected hairs. He thinks that in most recent cases its presence can be verified by a sufficiently careful search. It is worthy of notice that alopecia areata is most common when tinea tonsurans is most common, as in England and France.

As to treatment he prefers blistering in the early stages; later, strong parasitocides, as corrosive sublimate in solution. Pilocarpine internally, or under the skin, may be used with advantage.

[Crocker's view that most cases of alopecia areata are caused by the trichophyton tonsurans is not held by the American or any of the foreign schools. Many of the French dermatologists, with M. Besnier at their head, regard alopecia areata (La Pelade) as the result in some cases of a tropho neurosis, in others as due to a parasite as yet undiscovered. The epidemics of "la Pelade" that occur not infrequently in schools, camps,

<sup>8</sup> Lancet, February 28 and March 7, 1891.

etc., they regard as parasitic in character, but they are unable as yet to demonstrate the specific organism, and separate the affection distinctly from tinea tonsurans. REP.]

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, Monday, April 27, 1891, the President, Dr. FREDERICK I. KNIGHT, in the chair.

Dr. J. W. ELLIOT read a paper on

#### APPENDICITIS: A YEAR'S EXPERIENCE IN PRIVATE PRACTICE.<sup>1</sup>

Dr. M. H. RICHARDSON: I have been very much interested in these cases of Dr. Elliot. It seems to me that we do not as yet possess the experience or the knowledge to decide definitely in many cases of this disease. I was very glad when Dr. Elliot again brought up the subject, and I think that all the men who see many of these cases will agree—most all if not all—that we do not know as yet what to do in many of the cases. The subject is, of course, a very prolific one. We are getting everyday more experience, and yet we cannot lay down any fixed rule for treatment. I had the pleasure of listening to Dr. Worcester's brilliant paper, and I agree with Dr. Elliot that no such rule can be followed at the present time as to operate in every case as soon as a diagnosis has been made. My own experience since any general discussion of the subject has taken place here has been in the same general direction as Dr. Elliot's. It has been a sufficiently extensive experience to justify the assertion that I have already made, and I will add to it that not only among the men of the greatest experience in this disease, but among men of moderate experience, great doubt exists. In a large percentage of the cases I have seen in private practice it has been the old story of a moribund patient and a general peritonitis with a gangrenous appendix,—the story of delay and disaster. I refer now to the cases that have occurred among men who have not had a great experience. Quite a number of the cases I have seen have been practically moribund, and have died within a few hours after my visit. In that middle class of cases where there is doubt I do not think it is possible to predict either a recovery or death. Of course if it were possible to predict, we should know exactly what to do. I think those who see large numbers of cases will agree that a case apparently mild may in a short time become a fulminating case. I do not think we can set aside a certain number of cases, and say they are not worth considering surgically, because every case with the cardinal symptoms of appendicitis, no matter how mild, may become in a short time beyond the hope of surgical aid or recovery.

I think Dr. Elliot has laid down as well as can be laid down at the present time the rules or the symptoms by which he is guided. He certainly has expressed himself much better than I could have done. I was glad to hear the stress laid upon the general appearance of the patient. As I have remarked many times in my hospital service, you will have two cases that apparently are alike, if you should describe the

cases in words, because you would not be able to see any difference: but just as the experienced eye will tell the difference between two minerals very much alike, or as one could tell the difference between two faces very much alike, so there is an indescribable something which leads us in one case to operate and in another case to delay. The general appearance of the patient, the anxiety, the complexion, a general appearance of serious illness, perhaps the temperature and the pulse and the local symptoms, are alike; but it is, I think by the study of these appearances and symptoms that a man is enabled to decide what to do.

My experience in this disease is now quite large. I have seen in consultation between forty and fifty cases, many of which I have operated upon, and in a larger number I have advised against operation, and I feel to-day not so much in doubt as I did in the beginning, but I still feel in great doubt in a given case as to the best method of treatment. I wish we could lay down a rule by which we might be guided, but I do not believe we can yet lay down a general rule for the treatment of all cases. I do not believe that we ourselves would wish to be treated by any fixed rule of operation in all cases, and I do not believe in the summing up of all cases the mortality would be lessened by indiscriminate operations in all cases. Those who advocate this throw out the mild cases, or at least they say there are a large number of cases in which there is no question whatever of any surgical procedure; but, as I have said, those are just the cases, many of them, of which you cannot predict the ultimate course.

I should like to ask Dr. Elliot if he searches for the appendix in all cases. I have never seen the vermiform appendix yet in any of my operations. I have avoided any extensive searching in cases of circumscribed peritonitis, and have never seen the appendix or had any occasion to remove it. I have never operated where I have regretted it, and I have been fortunate enough never to have regretted advising against operation. Of course, I have been lucky in that respect, because it has happened that all the cases in which I have advised against operation have got well, excluding moribund patients. Many cases have died after operation, but I think even in such cases we had the satisfaction of having given the patient a chance; and after seeing some of the operations I have seen, notably some of Dr. Elliot's cases, I have felt encouraged in operating even in the most desperate conditions, for I have seen one or two of his where recovery has followed an operation where it seemed hardly possible that the patient could recover.

Dr. W. H. BAKER: I am very glad Dr. Elliot called attention to the fact that the temperature was not to be relied upon in some of the cases of purulent peritonitis. I remember the experience of years ago where some of the worst cases of purulent peritonitis were unaccompanied by any elevation of temperature. I think the physician who is looking for that symptom would go wrong many times, as Dr. Elliot has shown.

Dr. ELLIOT: I would say that I by no means make it a rule to excise the appendix. It is often a great deal safer to drain the abscess cavity. But when I look at these appendices which I have excised, with their great sloughing masses, their wide open perforations, their canals often increased in calibre, I realize what an advantage it is to excise the appendix, if it can be done without doing serious damage. In a general way, I think the appendix should be excised in

<sup>1</sup> See Journal, vol. cxxiv, p. 499.

the early operations, because in such cases the adhesions are not strong and are often broken during the operation, in which case the perforated appendix is opened directly into the general abdominal cavity. In the later operations, where a circumscribed abscess has formed, the appendix makes a part of the abscess wall, and should not be removed, as by tearing it out, the gangrenous parts of the intestines are so disturbed that they come in contact with the healthy intestines, and thus cause a spreading of the septic process. I have operated on six cases this year, and have excised the appendix five times.

I feel grateful for Dr. Richardson's sympathy about operating on patients where the only symptom was a bad facial expression. I think any one who has had patients with appendicitis or purulent peritonitis die under his care gets experience with this ghastly expression, although the temperature and pulse may be swollen, yet the condition is evident. I remember one of Dr. Richardson's cases, where pus collected in a perfectly flat belly, and all you could say about the man was that he was going to pieces, there being no symptoms; and at the autopsy, pus was found. I think that the sense of dissolution, or this expression of illness without any other symptom you can take hold of, is a thing to be cultivated in these cases. I think it is one of the most subtle and difficult things about the disease.

DR. RICHARDSON: There is a class of cases that I characterized, the first time I wrote a paper on this subject, as essentially favorable cases, in which there is a fulminating peritonitis, and death in the course of two or three days without any circumscribed collection of pus, with gangrenous appendix, the intestines covered with lymph,—all the symptoms that have been so many times described. In that form I have never operated but once; and in that case the diagnosis of obstruction was made, and the appendix only discovered gangrenous at the autopsy. In that class of cases the only thing to do must be the removal of the appendix and the flushing out of the abdominal cavity. I have seen quite a number of cases of this. The fatal cases which came to autopsy, where the patient when seen was moribund, have been in that class, and that is a class which it seems to me we have to consider more than any other,—a case that is going to die in two or three days, not with the abdomen full of pus, but general septic peritonitis and the nidus of infection in that gangrenous appendix; and if in all those cases one could operate in the first day, and excise the appendix and flush out the abdominal cavity, I have no doubt it would be very good treatment.

My point in regard to taking out the appendix was that, in localized collections of pus, in hunting round for the appendix with the finger, one would run the risk of separating recently formed adhesions, and doing more harm than good, converting a localized peritonitis into a general one; and in localized collections of pus all that is necessary is to drain. If, however, the appendix presents, and can easily be removed without exploring very much, it is a good thing to do.

DR. W. H. BAKER read a paper entitled

SMALL SUBSEROUS FIBROIDS OF THE UTERUS THE  
OF CASES OF GREAT INTOLERANCE OF THE  
BLADDER.<sup>2</sup>

<sup>2</sup> See page 190 of the Journal

DR. M. H. RICHARDSON: It is very surprising to me that so small a tumor should cause so much trouble. I have never removed so small a fibroid. I think in none of the abdominal hysterectomies which I have performed has pressure upon the bladder, which must have been very great, caused any such painful symptoms as in this case, and I think it is worth while reporting that so serious a condition of things can be caused by so small a tumor. I suppose the explanation that Dr. Baker has given seems very satisfactory, that the bladder gets tolerant by the slow growth of the tumor. I should like to ask Dr. Baker how long it has been since the operation.

DR. BAKER: About three months.

DR. RICHARDSON: It is possible that this may be a neurotic manifestation.

DR. BAKER: She is doing very well.

DR. RICHARDSON: Was there any question in this case of a neurotic tendency? Was she a woman in whom this might be a symptom?

DR. BAKER: I did not see any.

DR. CUTLER showed a specimen of

#### MYCOSIS PHARYNGIS LEPTOTHRICIA.

DR. KNIGHT: This preparation I asked Dr. Cutler to bring is one of mycosis of the pharynx, sometimes called mycosis pharyngus leptothricia. It is only within a few years that it has been recognized that certain cases of what we used to call chronic folliculitis of the pharynx are cases really of mycosis, and have been treated a good deal more successfully since their nature has been recognized. Clinically they are cases of chronic folliculitis, cases where you have not only a cheesy exudation, but a hardened cheese-like exudation coming out from the tonsil, sometimes sticking out much like little spears from all the crypts of the tonsils, and also from the base of the tongue sometimes, sometimes in other parts.

This particular preparation came from the tonsil of a young lady, a singer, who applied to a rather notorious advertiser here, a man who gives public consultations free and treats for pay, who told her that she had syphilis, and she did not know what syphilis was, and went home and asked her mother what syphilis was. She came to me and said she had been told that she had syphilis, but came to the conclusion that she had not it after she was told what it was. This girl suffered very little from it. Her voice remained good, but oftentimes it is a source of irritation which extends with slight provocation to the larynx, and very much impairs the voice.

The proper treatment is the removal, as far as you can, of the exudation, and then cauterizing in each crypt with the galvano-cautery point. That I have done in this case, and it bids fair to effectually stop the process. This particular form of what was formerly known as chronic folliculitis has been known as very obstinate and intractable, and until some such thorough means was taken, as the use of the galvano-cautery, in each individual spot, the treatment was not successful. Within a month or so I have seen a report from the hospital at Heidelberg, in which a gentleman in charge of the clinic there mentions a case in which he prescribed the use of cigarettes. He said he had noticed that nicotine had a very good effect when applied to these plaques locally; and the next case he had, a young lady, he advised her to take up cigarette smoking, and she smoked cigarettes a few

months and came back cured, but I do not think that would be a very good treatment to recommend.

DR. CUTLER: Leptothrix buccalis consists of rods and threads of different lengths,—some short, others long, but all straight. They are colorless, do not branch, and are generally found closely packed in bundles. Found abundantly about the mouth and teeth. The tartar at the base of the teeth contains them in large numbers. These threads are found in carious teeth, and are supposed by many to be the cause of the diseased condition. This statement admits of doubt, however. Besides being found about the teeth leptothrix is seen, mixed with epithelium from the mouth, on the tongue, and in catarrhal conditions of these parts it is found in abundance. Iodine stains the threads blue; the iodine-iodide of potash stains a blue-red.

DR. E. H. BRADFORD showed a specimen of

#### APPENDICITIS.

The case was operated on during the remission in a healthy laboring man of twenty-five, who had recovered from his third acute attack, and was in good health. The operation found the end of the appendix thoroughly embedded in a mass of adhesions to the small intestines. This was with difficulty freed from the small intestines, and the appendix was removed at an inch from its insertion in the caecum, where it seemed to be normal. The man made a complete recovery.

### Recent Literature.

*Les Fonctions du Cerveau: Doctrines de l'Ecole de Strasburg, Doctrines de l'Ecole Italienne.* Par JULES SOURY. 8vo, pp. xvi, 464. With four illustrations. Paris: Aux Bureaux du Progrès Medical. 1891.

The present volume is a reprint of critical digests that have appeared during the last two years in the *Archives de Neurologie*. About one-fourth of it is devoted to a review of the work of Goltz and his pupils, and the rest to the work of the Italians. At the present day Goltz is the chief opponent of the doctrines of cerebral localization, but he, from his knowledge, his talents, and his thorough and patient work, is worth an army. Soury, however, in his candid and thorough review of Goltz's work, shows that Goltz's own doctrines have furnished against himself decisive proofs in favor of the doctrine of localization; Goltz has himself shown that troubles of mobility and general sensibility are found especially in lesions of the anterior part of the brain, and troubles of special sensibility in lesions of the posterior part. The rest of the book is devoted to a study of the work of the Italians, and the author has accomplished a most praiseworthy task, in thus putting into a compact and accessible form the results of the great and valuable work which has been done in Italy,—a work too much neglected in this country. "The critic must recognize," he says, "the taste for careful observation, the passion for order, the shrinking from extreme solutions, the instinct for the experimental method, and, in brief, the solidity and the sobriety of the Italian genius. . . . It is no more permissible to ignore their work, than to ignore that of the Germans or the English." It may be added that in the study of the functions of the brain,

their work takes no mean place in comparison. The Italian doctrines are essentially eclectic, avoiding extremes, trying to reconcile opposing facts, and being based on experiment and clinical and anatomical observation. To the Italians is due the theory that the different functional areas possess, beside a special central region, common areas or zones of radiation where the centres overlap. In the dog the zones of sensory innervation seem to converge into a neutral territory, lesion of which causes impairment of all special and general sensibility. The cortex is the seat of the highest psychical functions, but not of simple sensations and organized motor impulses; the basal ganglia may supply in part the functions of the cortex. Different points of each functional sphere of the cortex sustain almost equivalent relations with the corresponding sense organs, so that substitution between different parts of the same centre is possible. Each functional centre sustains bilateral relations for the corresponding peripheral organs of sight, hearing and smell, but unilateral relations for the sensori-motor sphere. Morphological variations in the nervous elements of the cortex teach nothing as to their functions, but that may be gathered from their prolongations and their anatomical relations. The two types of motor and sensory cells of the cortex are so united and confused that the functions of motion and sensation have a common seat. The special functions of any area are due not to a special difference of nervous elements, but to the nature of the peripheral organ with which they are connected. There is no direct nervous transmission between two cells or groups of cells; the communication must take place through a vast diffuse network, made up of the ultimate ramifications of the axis cylinders. Golgi's musculo-tendinous nervous organs are undoubtedly the peripheral organs of the muscular sense. The activity of the brain, like that of the muscle, is attended, during the period of positive work, by an appreciable decline in the temperature of the brain substance, followed by a rise of temperature in the period of repose. These variations of temperature constitute true thermic oscillations, which correspond to the rhythm of processes of functional disintegration and reintegration of the nervous centres. Brain work is a form of energy, and intelligence has its chemical, thermic and mechanical equivalents. Such, in brief, is the summing-up which Soury gives of the doctrines maintained by the different Italian scientists. As an introduction to their work, and to the work of the Strasburg school, and as a guide to the original memoirs, the present volume merits high praise. We are glad to learn that the author intends to publish similar digests of the doctrines of the schools of Berlin, Vienna and Paris, and we hope he may be led to undertake a similar work for the school of London.

*Annales de Sciences Psychiques.* Paris: Felix Alcan, editeur. 1891.

This new journal, appearing every two months, is under the direction of Dr. Dariex, and is to be devoted to the various psychical phenomena of a so-called occult type, telepathy, presentiments, hallucinations, etc. Its aim seems to be about the same as that of the *Journal of the Society for Psychical Research*. The first number contains a letter from Richet, stating the objects to be pursued, an article by the editor on the method to be employed in telepathic observations, and a collection of various cases of telepathic hallucinations.

THE SUPPOSED CURATIVE EFFECT OF OPERATION, *PER SE*.

UNDER this title, Dr. J. William White, of Philadelphia, contributes a paper to the *Annals of Surgery* for August, 1891, which not only from its subject, but from the great number of authorities quoted, and from the rich experience of the writer, makes an article of interest and importance to both surgeon and physician. The author's attention was first directed to this subject by reason of his experience with the operation of trephining for so-called traumatic epilepsy.

During the past five years, with Dr. D. Hayes Agnew, he has trephined in 15 cases of supposed traumatic epilepsy. All but one recovered from the operation. The patient who perished was an imbecile and a confirmed drunkard as well as an epileptic. Death occurred from suppression of urine, probably secondary to etherization.

In one case a bullet was found imbedded in the brain substance. In another, an irregular portion of the internal table was dissected out from beneath the dura mater to which it was attached by cicatricial adhesions. In another there were projecting spicula of bone on the internal surface of the button removed and the adjacent portions of the skull. In two, marked sclerosis and thickening of the cranium were observed about the field of operation. In the remaining cases nothing abnormal was seen, notwithstanding which, they were, without exception, markedly improved by trephining; in two instances even to the point of apparent cure, no return of symptoms having been observed for eighteen months, and for two years, after operation. In the other seven the results were strikingly favorable, convulsions disappearing for weeks or months, although previously of more than daily occurrence.

The author has, in so far as this is possible, classified the cases in which operation *per se* seemed to be the main factor in bringing about a cure. These

cases are divided into three groups in accordance with the anatomical seat of the symptoms, or of the supposed disease. This brings them under the following heads:

(1) Operations for the relief of nervous phenomena, as epilepsy, insanity, paralysis, etc.; (2) Operations for abdominal and pelvic disorders, as peritonitis, tumors, etc.; (3) Miscellaneous operations. This classification is further carried out by grouping together (a) Those cases in which nothing whatever was found explanatory of the symptoms; (b) Those in which some departure from normal conditions was observed, but was so slight as to be apparently inadequate to explain the symptoms; (c) Those cases in which an apparently grave and irremediable condition was disclosed by an exploratory operation, but which notably improved or altogether disappeared after mere inspection or handling, no further surgical interference having been thought justifiable.

Under the heading of "Operations for the Relief of Nervous Phenomena," Dr. White has tabulated, including his own, 154 cases. Many of these are given in detail, and coming as they do from recognized authorities, are of much value.

In 56 cases of trephining for epilepsy nothing abnormal was found to account for the symptoms. Nineteen cases were reported in six months or less after operation; eleven cases were reported from six to twelve months after operation; six cases were reported from one to two years after operation; one was reported eight years after operation.

Twenty-five of these cases were reported as cured; eighteen as improved; in three cases it was mentioned that a relapse occurred later. In 30 cases of ligation of blood-vessels for epilepsy, 14 were reported as cured; 15 as improved; one died seven days after operation. In the fatal case the right common carotid artery was tied. No fit occurred after the operation.

In 10 cases of castration for epilepsy, all were reported as cured. One case was reported four months after operation; four cases were reported more than two years after operation; in five, the time when reported is not mentioned.

In nine cases of tracheotomy for epilepsy, two were reported as cured; six as improved; one as much improved, though death, in this case, followed in two months after the operation.

In 21 cases of removal of the superior cervical ganglia of the sympathetic nerves, six remained well at the end of three years; 10 were improved; five remained unimproved; two died soon after the operation, but not from its direct effect.

In six cases of incision of the scalp for epilepsy, nothing was found to account for the symptoms. Three of these cases were reported as cured at the end of three months or less; one was reported as cured at the end of one year; two were reported as cured at the end of two years; two other cases almost similar, were reported as cured.

Twelve cases of epilepsy are reported as cured by

such operations as stretching of the sciatic nerve, excision of the musculo-cutaneous nerve, cauterization of the larynx, circumcission, application of a seton to the back of the neck, tenotomy of the external recti muscles, burning of the scalp, puncture of the heart, etc.

Thirteen cases of spontaneous or accidental cures of epilepsy are also reported, at a time varying from two months to five years after the traumatism, which was a fall, a burn, a wound, an amputation for intercurrent injury or disease, etc.

Passing from the cerebral to the spinal region, Dr. White cites an illustrative case of his own. A man, aged fifty-five, was attacked on December 25, 1887, with severe pain in his arms and shoulders. A few days later there was weakness of the thighs, spreading rapidly down the legs to the feet, and upward on the body to the nipple line. In eight days there was absolute paralysis of the parts involved, including both sphincters, while at the same time the paralyzed parts became the seat of profound anæsthesia. Girdle pains developed, bed-sores made their appearance, percussion of the spine over the third and fourth vertebrae became painful. The reflexes were exaggerated, and light blows on the head in the direction of the spinal axis gave rise to frightful exacerbations of the girdle pains. In spite of every remedial measure, these symptoms increased in severity for ten months. An exploratory operation was then undertaken. Dr. White removed the spines and laminae of the first five dorsal vertebrae, opened the slightly thickened dura, separated some firm adhesions to the subjacent pia mater, explored the cord, and having failed to discover any pathological changes, closed the wounds in the dura and soft parts.

The girdle pain had entirely disappeared by the following day; sensation began to return the day after; voluntary motion in the toes after the eighth day; and so one symptom after another disappeared until the patient completely recovered, and is now earning his living by manual labor.

In the list of abdominal and pelvic disorders apparently cured by operation *per se* a number of instructive cases are cited. The experience of Tait, who has more than once drawn attention to the astonishing disappearance of tumors, often of large size, after a mere exploratory incision, and the corroborative testimony of von Mosetig are cited at length. Koenig's analysis of 131 cases of tubercular peritonitis treated by abdominal incision is carefully discussed.

In response to letters of inquiry upon the subject, Dr. White received many communications from prominent operators, the great majority of them containing notes of cases not previously published.

Under the heading of miscellaneous operations the author has given several of very diverse character. First are quoted cases of osteomalacia, cured, after weeks or months of confinement to bed, by either oöphorectomy or Cæsarean section.

Passing to another subject, the question of graduated tenotomy of the eye muscles for the relief of severe

nervous symptoms is carefully discussed. The author freely acknowledges the value of tenotomies in badly balanced ocular muscles, but he is none the less convinced that in numbers of instances of reported cures of chronic chorea, petit mal, and even delusional insanity, the effect of the operation *per se* is in large measure the potent cause of the supposed cure. This belief is founded, not alone on theory, but upon the fact that in certain cases of reflex nervous troubles a cessation of the symptoms has followed the tenotomy, although this has not produced perfect equilibrium. Again the relapses which may take place after a perfectly successful series of tenotomies would indicate that the nervous phenomena attributed to the insufficiency, for the relief of which the operations were made, were not correctly so attributed, and that the temporary relief must be ascribed to some other than the restoration of an imperfect balance of the external ocular muscles.

In seeking for a reasonable explanation of the phenomena observed in the above cases, the author has formulated the conditions which are common to nearly all of them. These are: (1) Anæsthesia; (2) psychical influence, or so-called mental impression; (3) relief of tension; (4) reflex action or the "reaction of traumatism." These influences were operative in the majority of cases, although not one of them except the last applies to the whole list.

With the idea that it was conceivable that a disease of the nerve centres, not reached by ordinary drugs, might be affected by agents of such volatility and diffusibility as ether and chloroform, the author instituted a series of observations upon a number of epileptics in various stages of the disease. All other treatment was withdrawn, ether was given to the production of full anæsthesia at intervals of from forty-eight to seventy-two hours. The results were either entirely negative, or in consequence of the withdrawal of their bromides the patients grew worse.

Since in the great majority of cases cited in this paper there were either undoubted symptoms such as are habitually associated with organic disease, or there was demonstrable and unmistakable evidence of such disease, it is necessary to believe, in considering the psychical influence of operation, that powerful impressions acting upon the emotional or intellectual nature may affect the organic processes of secretion, nutrition, etc., and may arrest pathological changes, and bring about reparative or recuperative action. Cases are cited in which such influences are clearly set forth.

The author holds that the normal equilibrium which we witness between the cerebro-spinal and the sympathetic systems, as respects their influence upon the blood-vessels, is obviously more or less interfered with when the brain transmits a more than wonted impulse, allowing the unrestrained action or paralyzing the influence of the sympathetic vaso-motor nerve. In this relation some curious cases of hypnotism, and some striking examples of the effect of the central nervous system upon the body, are cited.

The opinion is expressed that in many of the cases described there can be little doubt that relief of tension is an important factor in amelioration or cure. If it is assumed that preternatural tension exists in the cranial cavity, this would be relieved to some extent by trephining, and there would be but few exceptions to the rule that in each case something was done which lessened tension in some cavity or organ of the body. There are other cases, however, in which no such relief was obtained, and yet cure resulted from the operation. A diminution of the tension would manifestly alter the blood-supply to any important organ in the body, and with it the nutritive processes, local and general. Beyond this nothing definite can be said, except as it applies to cases of ascites in which, as in cases of hydrarthrosis, one tapping may prove permanently curative, because the original source of irritation and hypersecretion has already disappeared.

Under the head of reflex action, the author includes the "reaction of traumatism," as well as the effects of revulsion and counter-irritation. Verneuil has long since shown that very slight traumatism sometimes excites in the entire economy a general perturbation, and sometimes, by selection of the weak point, a sudden aggravation of lesions that are only slight or have slumbered. This same excitement, usually prejudicial, may occasionally be curative. In the case of spinal surgery above detailed, Dr. White believes that the local shock of the operation was promptly followed by a corresponding reaction in which the vitality of the tissues was raised sufficiently high to determine a return to the normal state. In this relation the reciprocal influence of one portion of the body on another is briefly discussed.

In considering abdominal tumors, attention is called to the possibility of the spontaneous disappearance of such tumors, the relation of this disappearance to the operation being coincidental; cases are cited in point. As to the cure or amelioration of growths thought to be malignant by merely exploratory operation, a long search through the literature of the subject has met with but little success.

The cure of tuberculosis of the peritoneum as the result of exploratory incision is explained on the ground that the removal of ascitic fluid allows the peritoneal surfaces to fall together and to acquire adhesions. The tubercles are then shut in between the coils of intestine, the omentum and the abdominal wall. They are thus surrounded by tissues in a high degree of activity which can now throw around them the limiting zone of young cells and eventually fibrous tissue, which, if the tuberculous process is not too far advanced, may effectually resist it and may cause it to retrograde, the process being analogous to that which we see imperfectly going on around a cancerous growth.

As a result of a study of the subject, the author believes the following conclusions are warranted:

(1) There are large numbers of cases of different grades of severity and varying character which seem

to be benefited by operation alone, some of them by almost any operation.

(2) These cases include chiefly epilepsy, certain abdominal tumors, and peritoneal effusions and tubercle, though the improvement in the latter is, perhaps, to be explained on general principles.

(3) Of the possible factors which, by reason of their constancy, must be considered, anæsthesia seems least likely to have been effective. The other three, namely, psychical influence, relief of tension, and reflex action, may enter in varying degrees into the therapeutics of these cases, and taken together, serve to render the occurrence of occasional cures less mysterious.

(4) The theory of accident or coincidence scarcely explains the facts satisfactorily.

#### INOCULATION OF CANCER.

THE official report of the meeting of the French Academy of Medicine, June 23d, which is at hand in the *Bulletin*, contains M. Cornil's presentation of the experiments made by a "foreign" surgeon upon two human subjects to test the possibility of the inoculation of cancer by grafts. The official report varies but little, and that in matters of detail, from the accounts previously received. The experiments, it seems, were made four years ago, a little subsequent to a similar experiment made in Germany by a Dr. Hahn, who announced his results at a meeting of the *Berliner medizinische Gesellschaft*, November 2, 1887. Hahn's experiment was repeated by Professor Bergmann, of Berlin, with similar results, and the subject was again referred to at the meeting of the German Surgical Society, April 25, 1889.

Professor Cornil's communication to the Academy, and the emphatic denunciation by his colleagues of the act which he reported, did not approve, has excited much comment in France. At about the same time much stir was caused in Germany by a demand made in the public press by a Dr. Leidig, a lawyer, for an explanation from Professors Hahn and Bergmann of their proceedings in regard to the inoculation of carcinomatous patients with particles of cancer in places not previously diseased, as already reported two and four years ago. So fierce a fire of indignation was kindled by this, that the German Minister of Education found it necessary to intervene and enforce the demand for some answer to Leidig's charges. As yet no answer has appeared, although Professor Bergmann is reported — we know not how truly — as maintaining the justifiability and propriety of the experiments as made by Dr. Hahn and himself. The *Deutsche medizinische Wochenschrift*, July 23d, contains, however, some remarks on the subject by Dr. Hermann Frank, who was assistant under Hahn at the time the grafts were made, which may perhaps be regarded as representing the form which a statement from Professors Bergmann and Hahn might take if one were made. Professor Ewald also, in the *Berliner klinische Woch-*

*enschrift* of July 18th, contributes a letter, of which the following are extracts:

"We have not to enter here into a discussion of the question as to the scientific result of the experiments and their importance for the cure and prophylaxis of carcinoma, and especially for the technique of the operation. On the other hand, we do not hesitate to declare that we wish to see such experiments on human beings, however important the questions on which they bear may be, performed, if at all, only by those whose scientific name and unquestionable humanity afford a guarantee that no harm whatever can accrue to the patients in question, and who accept the entire responsibility for this. The much-discussed communications of Messrs. Hahn and von Bergmann were made with all publicity, both in scientific associations and in the medical press. The names of these gentlemen afford every guarantee that the fundamental ethical principles of medical action were not violated in any way in the cases in question."

The Germans certainly seem to have acted with more circumspection in their operations than the "foreign surgeon" reported by Cornil, who had no regard for circumspection or medical ethics, even the most rudimentary. The patients in Paris seem not to have been at all in a hopeless condition, and the grafting was done, without consent, whilst the patients were anesthetized.

From an ethical point of view, as well as from that of common humanity, the French experiments deserve the condemnation which was instantly meted out to them. The German experiments, however, seem to rest upon a very different plane. The experiments were performed with the full consent and understanding of the patients, whose condition was not rendered in any sense more unfavorable by the operation. There is certainly, as has been claimed by the Germans, an enormous difference between the conduct of the anonymous surgeon and that of Messrs. Bergmann and Hahn, which had practically evoked no criticism from the profession until dragged into notoriety by a layman. Whatever may be thought of the propriety of these experiments, they are certainly valuable from a scientific point of view. Although we gain from them no additional knowledge as to the parasitic origin of cancer, the point has been definitely settled that fragments of cancerous tissue, when allowed to remain in contact with healthy tissues, may reproduce the disease, and the experiments emphasize the immense importance of taking every precaution during an operation to avoid exposing the living tissues to the juices or cells of the morbid growth which the surgeon is attempting to remove. This is a matter which hitherto has hardly been called to the notice of the surgical world.

Although we are not disposed to place the experiments of our German confrères in the same category with those of the unknown enthusiast whose zeal overcame his discretion and his humanity, we, nevertheless, feel called upon to caution scientific investigators that in dealing with human beings they are treading

upon dangerous ground, even when acting with the patient's consent, and that they should be blinded as to their duties towards the individual in their efforts to confer a boon on suffering humanity.

#### MEDICAL NOTES.

**THE CONGRESS OF HYGIENE.**—The International Congress of Hygiene closed on Monday, after a long discussion as to the next place of meeting. The congress finally decided in favor of Buda-Pesth.

**BOGUS MEDICAL DIPLOMAS.**—The Wisconsin State Medical Board has discovered that the Northwest is being flooded with fraudulent medical diplomas, purporting to be issued by the University of Victoria at Montreal. Fifty of these diplomas have been found in Wisconsin and South Dakota.

**THE POPULATION OF FRANCE.**—According to the last census the population of France was 38,095,150, including foreigners, which shows an increase of 208,584 over that of 1886.

**FATALITIES ON ENGLISH RAILWAYS.**—The railway fatalities during the course of last year have been returned at 1076 killed, and 4721 injured. The average of the fatalities is one in every seven millions of passengers carried.

**PRESCRIPTIONS FOR SALE.**—In connection with the question of the ownership of a prescription given by a physician to his patient, the *Lancet* copies the following advertisement from a newspaper. "Kidneys and Bladder.—Gentleman recently cured by noted titled physician (can be verified) will send full-est particulars and copy of the great specialist's 5 guinea prescription on receipt of 3s. 6d. Inexpensive remedies."

**SPECIAL RAILROAD FARES TO WASHINGTON FOR THE MEETING OF THE CONGRESS OF PHYSICIANS AND SURGEONS.**—The Trunk lines, the New York and Boston lines, the Southern Passenger Association, and the Central Traffic Association will transport persons from points on their lines to Washington and return at the price of one and one-third the regular fare on the following conditions: (1) There must be an attendance at the meeting of not less than one hundred persons holding special certificates. (2) The going ticket must be purchased within three days before the opening date of the meeting. (3) Each person availing himself of the concession must pay full first-class fare going to the meeting, and must obtain a certificate from the agent of whom the ticket is purchased. (4) Those holding such certificates, when countersigned by the proper officer at the Congress, can obtain return tickets at one-third the highest limited fare. Certificates are not transferable, and the return tickets secured upon certificates are not transferable. If any of them are sold or transferred, they must be redeemed at the highest first-class rate by the person making such sale or transfer. No refund of

fare will be made on account of any person failing to obtain a certificate. Those who wish to avail themselves of this method of obtaining reduction in fares, should present themselves at the office for certificates and tickets at least thirty minutes before departure of trains. It is absolutely necessary for each passenger before starting to obtain a certificate from the agent of whom the going ticket is purchased, otherwise he can obtain no reduction in the return fare. There will be no stop-over privileges on the return tickets, which must always be by the same route as the going ticket. Members may obtain tickets on these conditions for their wives and members of their families, as well as themselves.

Dr. Samuel S. Adams, 1632 K Street, Washington, D. C., in charge of railroad matters, wishes to be notified by members, without delay, if they intend to avail themselves of this method of obtaining reduction in fare, and also whether they expect to be accompanied by any members of their family who will also desire to avail themselves of such reduction. Early in September the Committee will inform them by circular, as to whether one hundred persons or more have sent notice that they will avail themselves of this method of obtaining reduction, and will obtain special certificates for the purpose. In case there should not be one hundred persons who indicate their intention of doing this, only the ordinary reduction of rates on round-trip excursion tickets can be obtained by those going to the Congress.

**THE NEW EXPLOSIVES.**—Workmen employed in manufacturing the new explosive melinite, says the *British Medical Journal*, are liable to present serious symptoms of poisoning. The earlier symptoms are itching of the conjunctiva, loss of appetite, cough, and sometimes hæmoptysis. The patient then begins to suffer from severe asthmatic attacks, during which the heart's action becomes very rapid. The face, hands and hair are stained yellow, and picric acid is found in the urine also. In one man who died of intercurrent influenza, parenchymatous nephritis was found after death, and picric acid was present in the liver. The part of the process of manufacture which produces these effects is that in which carbolic acid is added to nitric acid; nitrous fumes are liberated, and at the same time, owing to the heating of the mixture, some picric acid is volatilized.

**CHOLERA IN CALCUTTA.**—From Calcutta for the week ending May 30th, 45 deaths from cholera were reported; for the week ending June 6th, 4 deaths. The weekly death-rate of Calcutta during the first quarter of the year, varied from 26.5 to 57.2 to 1,000 inhabitants; for Madras, 32.7 to 44.3; for Bombay, 24.9 to 32.8. The increased death-rate at Calcutta is to be ascribed partly to a fatal fever and partly to cholera. The latter disease received considerable accessions from the numbers of pilgrims who resorted to the city for the celebration of the twenty-seven year religious festival. It prevailed chiefly among the pilgrims. At Calcutta the total number of deaths

from cholera during the months of January, February and March, was 810, while the average number for the same period during the past ten years, was 455.

**A VERDICT AGAINST A PHYSICIAN.**—In an English town recently, two boys were found trespassing in a garden. The proprietor, who was a doctor, took them to his surgery, and by way of punishment, painted their faces with lunar caustic, producing a representation of a moustache and an imperial. The boys were then released. On their arrival home their faces were dressed with oil, but nevertheless, they complained very much on the following day of pain, and one of the boys was sent back from his work as his employer objected very much to his facial adornment. The parents afterward brought an action against the doctor. Medical evidence as to the nature of the injuries was given, and the doctor was fined five shillings, with costs.

### Miscellany.

#### THE INFLUENCE OF INTESTINAL ANTISEPSIS IN THE TOLERANCE OF CERTAIN DRUGS.

FÉRÉ has observed the favorable effect of intestinal antiseptics in persons who are taking continued doses of bromide of potassium, in causing the disappearance of the disturbances attributed to its accumulation, and in particular the cutaneous manifestations.<sup>1</sup> The antiseptics has been persevered in for nine months, and though the patients take daily one drachm of naphthol and half a drachm of salicylate of bismuth, no annoyance has been experienced. The relative tolerance of these drugs is therefore considerable. It would appear that one may regard as absolute the benefits which they confer on those taking bromide of potassium. There are several persons who have taken as much as half an ounce of the bromide daily, not only without injury to their general health, but with great advantage to their convulsive attacks. But borax, which has been employed in epilepsy, causes also gastric disturbance and eruptions. Gowers has shown that it may occasion an outburst of psoriasis, and FÉRÉ has seen eczema show itself. These eruptions may appear when doses of fifteen or twenty grains are prescribed, yet occur more frequently and with greater intensity if a drachm or a drachm and a half be given daily. But in the case of two persons, without stopping the borax, which acted satisfactorily on the seizures, a generalized eczematous eruption disappeared in course of a few days when the naphthol and salicylate of bismuth in the doses mentioned were prescribed. In a third patient, the cure of the boric eruption was obtained by administration of the salicylate of naphthol (Béto) in the dose of seven and a half grains daily. Before he used these antiseptic substances he never obtained the cure of the boric eruptions unless it was discontinued, and the same with those due to bromide. It is probable that this effect of intestinal antiseptics in the tolerance of drugs is not limited to those named, but may be had recourse to under other circumstances, and in particular against drug eruptions combined with gastro-intestinal disturbance of toxic origin.

<sup>1</sup> Edinburgh Medical Journal, August,

## A CASE OF ARBITRATION.

LAST week we took occasion to note the result of a recent trial for malpractice, says the *Journal of the American Medical Association*, and on account of its fairness and justice published the decision of the appellate judge who heard the case.<sup>1</sup> This week we note another instance in which suit was brought against one of the most prominent physicians in this city, and by consent submitted to a board of three physicians chosen to act as arbitrators. A large amount of testimony was heard, the trial occupying an entire week. In the finding the arbitrators unanimously decided that the defendant was not guilty as charged by the plaintiff. The plaintiff alleging that the defendant had improperly diagnosed and treated the case. The arbitrators found the defendant's diagnosis to be correct and the treatment in perfect accord with the laws of medical science.

The method of settling disputes by arbitration is one commonly adopted by merchants and others engaged in the common business affairs of life, and is highly satisfactory to all concerned except the attorneys. This is the first instance within our knowledge where this plan of settlement has been adopted in a case where an individual believed himself unskillfully treated by a physician.

A NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA.<sup>2</sup>

DR. WIESENDENGER describes in the *Journal für Zahnheilkunde* a new method of producing anæsthesia by the application of cold, the characteristic feature of which is that it is not the cold-producing agent which touches the desired part, but a metallic tube or chamber which is cooled by carbonic acid. The cold may, according to the requirements of the case, be regulated from the temperature of cold water to one sufficiently low to cauterise. The first symptom of this artificial cold is anemia of the cellular tissue, producing a slight sensation of burning, which is followed by anæsthesia, which lasts from one to two minutes and then disappears without any ill effects. As the instrument may be manufactured of almost any shape, it is evident that this new method may be used for a variety of purposes. The simple turning of a tap will regulate the stream of carbonic acid to any degree of temperature down to four degrees Fahrenheit. No moisture is produced. In using this cold for the purposes of cauterizing, the surgeon has the advantage of producing anæsthesia at the same time. When applying it to any of the internal cavities, such as the mouth, it is necessary to have the parts carefully dried, as the tissues would otherwise adhere to the instrument. Dr. Kummel applied the method in the case of a boy in the Maria Hospital, at Hamburg, with such complete success that the boy looked on without moving a muscle while a deep incision of twelve centimetres in length was made in his thigh. Other gases which can be brought into a fluid state may be used in place of carbonic acid. The carbonic acid which has been used for the purposes of anæsthesia may be led into a vessel which has been tested to a pressure of three atmospheres, and is provided with a manometer and safety valve, whence it could be used as a motor agent or for preserving food. An iron bottle of fluid carbonic acid

at a pressure of fifty atmospheres is sufficient for fifty operations,—and costs but a dollar or two. The instrument for the application of cold to the tissues costs about eight dollars.

## QUESTIONS ASKED AT EXAMINATIONS IN MEDICINE.

In a letter<sup>1</sup> criticising the questions asked by the New Jersey State Medical Examining Board, Dr. H. C. Wood calls attention to the dangers to medical education which may result from absurd questions on examination papers. A student generally knows what kind of questions he is likely to be obliged to answer, and prepares himself accordingly.

State medical examining boards must exert great influence upon teaching faculties, and there always is danger that medical schools shall prepare men for examining boards rather than for practice of medicine. It, therefore, behooves examining boards to take great care that their questions have close relations to practical medicine, and especially to modern practical medicine.

The questions asked are of such a character that, if this examination is to be the type, one of two things must happen: thoroughly trained graduates of medical schools of the first class must either fail altogether, or at least go to the bottom of the list, or else medical colleges will have to strive to make mediæval lumberattics of the heads of their students, much to the disgrace of American medicine and the detriment of American communities. Dr. Wood affirms that, although he is an editor of various editions of the "United States Dispensatory," and the author of a text-book on therapeutics, not only could he not, off-hand, answer the questions asked in materia medica and therapeutics, but that he would be ashamed of himself if he could.

On the one hand a candidate might be thoroughly familiar with almost any one of the high-class modern treatises of therapeutics and not be able to answer these questions, whilst on the other hand these questions could be answered by one who had no valuable knowledge of practical therapeutics.

For instance, he says, "Take Question I: What is dialyzed iron, and how is it prepared? Dialyzed iron is a worthless preparation of iron, which has never been recognized by the United States Pharmacopœia, and is, I believe, no longer used by physicians who are any way near abreast of the times. In my lecture I simply mention it as a pharmaceutical curiosity that is worthless. It seems to me a first principle of examinations by medical boards should be that attention must be confined to official preparations. If the candidate is to be asked a lot of foolish questions upon every kind of preparation, invented by some perhaps semi-addled pharmaceutical brain, how is he to gain any knowledge? He must be forever running after the chaff that is blown away by his teachers.

"Then again, Question III: How many practical doctors can give the specific gravity of chloroform, and what use would it be to them if they could?

"Question IV: Give the formula and mode of making camphorated tincture of opium. If there were a candidate for graduation in the University of Pennsylvania who could answer this question, I would cer-

<sup>1</sup> See page 178 of the JOURNAL.

<sup>2</sup> *Lancet*, August 1st.

<sup>1</sup> *University Medical Magazine*, July.

tainly examine him most severely to see whether he had not grasped at the shadow and lost the substance of true knowledge. Our men are all taught that the strength of paregoric in opium is two grains to the ounce, that it contains some camphor; and that is all that it is necessary to know about its materia medica or pharmacy.

"(Question V: Give the formula of the compound cathartic pill. I doubt whether there can be found a doctor in Philadelphia, in sufficient repute to have a practice of three thousand dollars a year, that could answer this question: to know the effect of this conglomeration of cathartics is what the medical practitioner needs. Again, why should a doctor be required 'to describe infusion, decoction, maceration and digestion,' and not one word asked about the physiological or remedial action of such remedies as opium, quinine, alcohol, digitalis, mercury, arsenic, veratrum viride, aconite, strychnine, nitrates, cathartics, tonics, emetics, or almost any other drug of any value? Indeed, the only drug whose general effect upon the human system is inquired into is one that is not official."

### THERAPEUTIC NOTES.

SULPHONAL is regarded as one of the most reliable and safest hypnotics; but that there is a certain amount of danger, was shown by Bresslau.<sup>1</sup> The patients were lunatics, and had been taking the drug for a considerable time in good doses, and borne it well until symptoms of disturbance set in, these being great constipation, dark-brown urine, slow, or in some cases rapid but feeble pulse, discolored patches resembling purpura on the limbs, and great prostration. In several cases which ended fatally, the cause of death was heart failure, with oedema of the lungs.

### A READY METHOD OF MAKING GLYCERIN SUPPOSITORIES.<sup>2</sup>

R. Stearic acid	5 gm.
Carbonate of sodium (crystallized)	2.5 gm.
Glycerin	120 to 150 gm. M.

The stearic acid in powder is warmed, and the carbonate of soda added with a little water and glycerin. The rest of the glycerin is then warmed and added, and the mass cooled in moulds.

DERMATOL. — Heinz and Liebrecht<sup>3</sup> have given the name dermatol to the basic gallate of bismuth, which is said to be a fine, odorless, insoluble, saffron-yellow, non-hygroscopic powder, unchangeable by air or light. The remedy has been used with good results as a substitute for iodoform in surgical, gynecological and dermatological practice. It commends itself as an innocuous, sedative, anti-epileptic drying powder.

VALERIANATE OF ANTIPYRIN. — The following formula<sup>4</sup> may be used to prepare this salt, which is of value in certain nervous cases:

R. Antipyrin	gr. xviii.
Aq. destillat	℥ss. and ℥ss. sol.
℞. sol. et add.	
Sol. val. (see p. 117)	℥ss. xv.

Shake well and stand aside to allow the salt to crystallize.

VALERIANATE OF ANTIPYRIN AND QUININE. — Sochaczewski gives the following as the best method of preparation:<sup>5</sup> Dissolve 10 gm. of valerianate of quinine in a sufficient quantity of 90 per cent. alcohol to give a thoroughly saturated solution. Dissolve 10 gm. of antipyrin in the smallest possible quantity of distilled water. Mix the solutions in a crystallizing dish and apply heat, being careful that it does not go beyond 122°. The crystals form and no sub-product is obtained.

### Correspondence.

#### "MIRACLES AND MEDICINE"—A REPLY.

MAGNOLIA, MASS., August 14, 1891.

MR. EDITOR:—In your number for July 30th is a letter from Prof. Thomas Dwight, M.D., upon your editorial notice of my recent paper, "Miracles and Medicine," which seems to call for some reply.

I pass the abuse contained in its preface. Such phrases as "gross misrepresentation," "absolutely untrustworthy," "absolutely false statements," "glaring misstatements," "bitterly prejudiced and unjust," and the like, can hardly fail to strike the thoughtful reader as much more like the hysterics of a disquieted zealot than the judgments of a fair critic; and I take up at once the three or four statements which he singles out from the hundreds contained in the two chapters to which he refers.<sup>1</sup>

The first of these which he attacks is that "the School of Salerno was held in aversion by multitudes of strict churchmen;" and to this fact, which is well known to every unprejudiced student of medical history, he opposes the following statement and argument: "This was unlikely, but not impossible. The school was founded by the Benedictines, who certainly were considered strict churchmen." This statement and argument give us at once a test both of the doctor's accuracy and his logic. First, as to his accuracy. If there is one thing in the history of medical instruction which is settled, it is that the Benedictines did not found the School of Salerno. There was an old claim to that effect, which probably arose at the neighboring monasteries of Monte Cassino and La Cava. Sprengel carelessly admitted it into his history of medicine about the end of the last century, and sundry compilers have followed it since; but now that the matter has been carefully investigated, every leading authority, whether Catholic, Protestant, or purely scientific, has abandoned it. Haeser and Baas, the most eminent historians of medicine in Germany; Darenberg, Director of the Mazarin Library, the foremost recent authority in France; Renzi, eminent in Italy; and, finally, Dr. Payne, of St. Thomas's Hospital, in his admirable article on medicine in the latest edition of the "Encyclopaedia Britannica,"—all these declare this theory to be without foundation. The words of Dr. Payne are as follows: "It has by recent researches been clearly established that the celebrated *Schola Salernitana* was a purely secular institution. . . . All that can with certainty be said is, that a school or collection of schools gradually grew up in which especially medicine, but also, in a subordinate degree, law and philosophy were taught."

Nor is this all; the blunder which Professor Dwight makes in his zeal as a champion of the church is exposed by no less a personage than Father Denile, sub-archivist of the Vatican, the latest and greatest among Roman Catholic historians of the European universities, who says that he is "forced to confess that the beginnings of the School of Salerno remain veiled in darkness," and that "it is impossible to say whether its origin was clerical or lay."<sup>2</sup>

<sup>1</sup> The articles are, "New Chapters in the Warfare of Science," Popular Science Monthly, May and June, 1891.

<sup>2</sup> See Denile, Die Entstehung der Universitäten, p. 232. For Darenberg, see his La Médecine, pp. 132, 133. See also Haeser, Haas, Renzi, *et al.*

<sup>7</sup> Chemist and Druggist.

So much for the professor's accuracy: next, to his logic. Grant that all these leading modern authorities are wrong and that the professor's mere *ipse dixit* overrides all the proofs they can cite; what conclusion may we draw? The conclusion which the professor draws is as follows: The Benedictines founded the School of Salerno; the Benedictines were strict churchmen: *argui*, "Mr. White is guilty of gross misrepresentation" when he says that "The School of Salerno was held in aversion by multitudes of strict churchmen." There is no need to discuss such reasoning;—surely any Harvard Sophomore chopping logic like this would be plucked at once.

So much for the professor's accuracy and logic. I now take his next criticism as an exhibition of his fairness. My statement was that "Pope Innocent III, early in the 13th century, forbade physicians, under pain of excommunication, to undertake medical treatment without calling in ecclesiastical advice." Professor Dwight attacks this statement, first, by a quibble, saying, "In point of fact, what is referred to was not done by Innocent III, but by the Fourth Council of the Lateran during his reign." I submit to the candid reader that this reply of the professor indicates either disingenuousness, or ignorance of the history referred to. For nothing is more usual or more just among historical writers than to attribute important church decrees to the Popes, who carried them through, even though they were passed upon, as a matter of form, by a Council. For example, the future historian will certainly, on this principle, attribute the Infallibility dogma to Pius IX. How much more natural, then, to attribute the decree above-mentioned to Pope Innocent III. He was the most powerful pontiff who ever sat in the chair of St. Peter, and, with the possible exception of Gregory VII, the greatest. He not only called the Fourth Lateran Council, but he presided over it, in his own city, at his own basilica, to carry out his own policy, in accordance with his own programme, as every scholar of church history well knows. As well say that the Battles of the Wilderness were not fought by General Grant, but by the military councils he called to receive his orders; or that the Emancipation Proclamation should not bear the name of Abraham Lincoln, but those of his cabinet who considered his draft and revised it. Very naturally, then, does the professor, after indulging in this small piece of casuistry, dismiss his own statement as "a detail of little consequence."

He next goes on to complain that my statement gave "an entirely false impression"; and he says "What was decreed was that a physician, on being called to a case, should advise the patient to attend to the state of his conscience, that is, to send for a confessor; but this in no way implied that the priest was to interfere with the treatment of the case." Here again the professor shows himself either unacquainted with his authorities or exceedingly disingenuous. The context of the canon, while it shows that this ecclesiastical advice was nominally for the prescription of spiritual remedies, shows just as clearly that these remedies were expected to help the body. This is explicitly stated as a ground for the canon: "*Cum infirmitas corporalis nonnunquam ex peccato proveniat*"—"Since bodily infirmity sometimes arises from sin," it begins, the physician of souls should be called, "so that, after provision has been made for the sick man's spiritual care, there may more wholesomely follow the remedy of bodily medicine, since when the cause ceases the effect ceases."

Here, then, is my whole contention: the mediæval theology attributed disease largely to human sin, which brought upon the patient the wrath of God or the malice of Satan; hence though the Church authorities were forced to recognize the medical profession, their constant effort was to keep it subordinated to the priestly function. The *Agnus Dei* and fetiches of every sort in the vast repertory of "Pastoral Medicine," were constantly urged upon the faithful by every means, from the voice of Pope Paul II down; and this, of course, interfered constantly and

greatly with the evolution of scientific medicine. I feel like thanking the professor for enabling me to bring out this matter so clearly.

Dr. Dwight's next attempts to show that I am wrong as to the penalty inflicted on a physician for not calling in a priest, and he urges that it "was not excommunication, but prohibition to enter a church, which was a very different thing from excommunication in those days." This is a nice point, and in splitting this particular hair, the professor is half right and half wrong; half right, because the penalty, technically, is as he has stated; and half wrong, because exclusion from the church, "in those days," was not "a very different thing from excommunication"; it was in any case a very serious calamity, and must lead directly into excommunication, if the sinning physician did not confess and do penance. The penalty was thus the incipient stage of excommunication; it must have been ruinous to the business of any physician who incurred it.

But the doctor is welcome to all the advantage he gains from this exquisitely minute point of casuistry. For, taking the case as he leaves it, can any medical practitioner fail to see what was involved in the church penalty? What must have been the status of scientific medicine when theologians solemnly endeavored to force every physician, in every case, to postpone every attempt at rational cure until a priest had been called in to apply "pastoral medicine," whether the little wax *Agnus Dei*, which Pope Paul II. insisted was of such use in obstetrics, or water in which St. Remy's ring had been dipped, so useful in fevers, or any other of the ten thousand fetiches in vogue during the "Ages of Faith."

But Dr. Dwight calls attention to another part of the canon, which orders that the "physician should advise no remedy for the food of the body that might be to the injury of the soul," and says, "This, indeed, is a check on medicine, but a most salutary one." The doctor's reading must have been limited, indeed, if he really thinks this theological check "salutary." For theologians in those days thought many things "to the injury of the soul" which all physicians think absolutely necessary. For example, St. Nilus, St. Ambrose, St. Gregory of Tours, and a multitude of other great theologians, thought taking any medicine at all "an injury to the soul"; and they held this view because taking medicine involves a preference of human over divine methods of cure. Let me give the doctor one theological statement on this point, from a greater authority than any one of the above, an authority, not only sainted, but infallible in matters of faith and morals, Pope Gregory the Great. He tells us: "The precepts of medicine are thoroughly contrary to sacred knowledge; they recall us from fasting; they forbid study; they withdraw us from meditation. Therefore, whoever gives himself up to physicians denies himself to himself."<sup>4</sup>

Such are among the things "to the injury of the soul": the doctor is quite right; the anathema and excommunication at the end of the chapter he cites, might easily, by a zealous theologian, be applied to these.

The doctor next takes up the case of Vesalius. I had attributed a considerable part in the events which drove him into exile to ecclesiastical hostility, and, in doing so, followed such leading authorities as Boerhaave, Albinus, Parc, Langnet, Haeser, Baas, Kingsley, McRae, and many others. Against the well-considered judgments of all these the professor puts—his own, as follows: "The talk of Vesalius having been driven to exile and death is absurd." To bolster up this *ex cathedra* judgment he follows it with sundry statements which will astonish any competent historical scholar by their vast and varied misinformation. He tells us that Vesalius, "so far from being oppressed by the Church, flourished in Italy and Spain, the two countries where she was strongest." Here the doctor yokes together a misstatement and what looks much like a piece

<sup>4</sup> Ut postquam fuerit infirmo de spirituali salute provisum, ad corporalis medicinas remedium salubriter procedatur, cum causæ cessante cesset effectus.

XL, and, for the whole passage cited, Poly., 1-3, lib. 29; Item, *Gregorius in Expositione beati Job*, lib. 30, c. 27. For the utterances of St. Nilus, Gregory of Tours, and others to same effect, see authorities cited in *Popular Science Monthly*.

of ignorance. First, How Vesalius "flourished in Spain" is seen by the fact that Vesalius himself complained that in Spain he could not obtain a subject for dissection, not even a skull; secondly, it is misleading to say that Italy was one of "the two countries in which the Church was strongest,"—so far as the country outside the States of the Church was concerned. The weakness of the Papacy in keeping down hostile opinion in various parts of Italy was a frequent taunt throughout Europe during the Middle Ages. Dante bears witness to this feeling. In Germany, during the Reformation, it constantly appears. Martin Luther pointed one of his most bitter diatribes with this acknowledged fact; and, in our own time, Guizot, a historian pre-eminently fair toward the older Church, mentions the widespread hostility of Italy to the Papacy as a cause why the Crusaders who passed through that country became less devoted to the Church. The doctor dwells with unctious upon the fact that Vesalius professed anatomy at Padua, Bologna and Pisa, evidently thinking that this proves him to have been on good terms with the Church! It really raises rather a presumption against any such harmony. Those Universities were constantly restive under theological and ecclesiastical interference, and not unfrequently preferred a man who had braved the Church, in order to advance his own department of science, over a candidate who carried ecclesiastical favor at the expense of his science; this is exactly why so many men of note in these same universities of Padua and Pisa afterward stood so firmly by Galileo.

The doctor next ventures an explanation of his own, saying, "He (Vesalius) no doubt met with great opposition, but probably chiefly from his own profession." Now, I had myself called attention to this jealousy among the devotees of ultra-conservative methods in the medical profession, as a fact which rendered clerical opposition all the more likely. For there is nothing better known in the relations between theology and medicine than that the theological and ecclesiastical powers have steadily shown a strong disposition to ally themselves with the party opposing progress in medical science. The history of inoculation, vaccination, and even of the use of anesthetics in obstetrical cases, abundantly proves this; and, not only in Roman Catholic, but in Protestant countries. These reasons, then, which the doctor gives for disbelieving in clerical interference against Vesalius are really reasons for believing it.

But the climax of the doctor's learning is reached in the following triumphant statement: "Be that as it may; it is certain that, at Jerusalem, he (Vesalius) received letters from the Senate of Venice, offering him the professorship of anatomy at Padua, which disposes effectually of Dr. White's statements about his being driven to exile and death." Is Dr. Dwight so ignorant then, not only of the general history he expounds to us, but even of the history of his own profession, as not to know that Vesalius's call by the Senate of Venice makes for my contention and against his? Has he never heard of the long struggles of the Venetian Senate through the Middle Ages and afterward with the Roman Curia on the question of commerce with infidels? Does he not know that, time and again, not only the Senate, but individuals at Venice, braved the Papal authority on this and other points? Has he never heard how the Venetian Senate circumvented the Roman power in the matter of the interdicts? Did he never hear of Father Paul Sarpi, "Theologian of Venice," who braved the Papacy and was unflinchingly backed by the Senate? and how when Father Paul was left for dead by the emsars of Paul V, the Senate stood by him all the more firmly, and how they made it treason for a priest to read a papal bull publicly without their previous authorization? And, on this very point, has he never heard how, as early as 1567, the Venetian Senate braved theological feeling by giving permission for a fated number of dissections each year, and a little later, called Mondinus to make them? As a matter of fact, then, the calling of Vesalius to succeed Aculapio by the Senate of Venice, so far from "disposing effectually of Dr. White's statements," raises a presump-

tion that Vesalius was a man after the Venetian Senate's own heart,—a man who investigated anatomy and taught it by the best methods, despite theological tradition and ecclesiastical opposition.

Dr. Dwight next wheels into place what he evidently considers his heaviest piece of artillery,—with the usual prelude of hysterics, such as "glaring misstatement," "absolute untrustworthiness," "utterly false," and the like.

My statement which brings out these frantic utterances is that "Boniface VIII prohibited dissection as sacrilege"; and the doctor proceeds to give the text of the decree "*De sepulchris*," and to interpret it correctly, saying, "It forbids the eviscerating and boiling the bodies of the dead for the purpose of bringing the bones home to the country of the departed." He then goes on to say, "Neither in this decree, nor anywhere else, so far as I have been able to learn, is there any prohibition of dissection."

Now let me ask, What does the professor think was Pope Boniface's reason for issuing a special decretal declaring that persons taking the flesh from skeletons under the circumstances named, should be "by the very act excommunicated"? Why denounce so terrible a penalty against so small an offence? No one can suppose that Boniface thus "dealt damnation round the land" for his own amusement or out of sheer wantonness. There are but two reasons which can possibly be assigned. The first is, that the Crusaders might not be burdened by carrying the bones of dead leaders; but this is disproved at once by two facts: first, it does not apply to Crusaders any more than to others; and secondly, the Crusaders were distinctly authorized to bring back the bodies of their dead, if they brought them back whole, and did not cut them up for easier transportation. The only other reason then is, that the decretal enforced, developed and made specific, the great and well-known theological opposition to the dissection of human bodies.

Regarding this general subject, let me quote the main passage among those which have so excited my critic:

"Other developments of thought in the church were hardly less fatal to the evolution of medical science. First of these was a widespread Egyptian and Oriental theory, mainly transmitted through the Jewish sacred books, as to the unlawfulness of meddling with the bodies of the dead. And when to this was added the mystic idea of the human body as the temple of the Holy Ghost, and a dread of interfering with it lest some hindrance might result to its final resurrection, there came an addition to the mysterious reasons which forbade men to pursue anatomy by means of dissection. Tertullian denounced the anatomist Hierophilus as a butcher; St. Augustine spoke of anatomists generally in similar terms. The threat of excommunication launched by Pope Boniface VIII, against those guilty of dissection, was simply a development of this feeling."<sup>6</sup>

Now, if Professor Dwight will look into the third edition of Theser, he will see the connection between this bull of Pope Boniface and the general theological hostility to dissection. He will find that the usual manner of freeing the skeleton for easy transportation was to cut the flesh from the bones, using the boiling as an auxiliary process. Hence it is that all authorities of note—until Professor Dwight—have considered Pope Boniface's bull as virtually levelled at all dissections. It is a simple argument *a fortiori*. If a man's body might not be cut apart in order that it should be brought back to holy ground in which reposed those dearest to him, how much less might anatomists cut up both flesh and bones to feed a curiosity and advance a science against which such great churchmen as St. Nilus, St. Ambrose, St. Gregory of Tours, St. Bernard, and a multitude of lesser lights had protested. These historians reasoned just as men did in England in the last century: when the penalty of death was denounced against any person stealing five shillings, they took it for granted that it

<sup>6</sup> For the Decretal "*De Sepulchris*" see the Corp. Jur. Canoniel et ord., among the extravagantes.

<sup>7</sup> White, "New Chapters in the Warfare of Science, Miracles and Medicine," Popular Science Monthly for May, 1891.

was equally severe against any person stealing twenty shillings.

Yet in a small, technical way, Professor Dwight is correct, and Haeser, in his last edition, to stop the mouths of the gainsayers, concedes thus much; but the fact remains that this bull of Pope Boniface was part of that theological hostility to dissection which lasted in the Church over fifteen hundred years.

If there were "no such opposition to dissection," how can the professor explain the fact that sundry universities, in order to enjoy the benefits of anatomical demonstrations, once a year took pains to secure permission of the ruling Pope, as did the University of Tubingen from Sixtus II in 1482—or from rulers so independent of the Pope as Emperor Frederick II, who, though the greatest enemy the mediæval papacy ever had, only ventured in 1238 to give permission that the body of a dead criminal might be dissected once in five years; or from bodies as bold as the Senate of Venice which, in the 14th century, allowed one dissection a year?

And finally, Professor Dwight says: "As to Dr. White's second conclusion, that 'in proportion as the grasp of theology upon education tightened medicine declined, and in proportion as that grasp was relaxed medicine has developed,' I have something to say."

I will give this "something" of the professor in his own words: "The schools of Salerno, Padua, Rome, Naples, Pavia and Pisa show that the country where anatomy flourished, was just where the grasp of theology was strong."

We have already seen that only Dr. Dwight's want of knowledge regarding the history of medical schools and medical science could excuse him for framing this sentence. It was exactly in the great majority of these schools that theological authority was at times weakest, and it was exactly at such times that medicine as well as other sciences made the greatest leaps forward. Strange as it may seem to the doctor, there were universities in France and Germany where theological control of science was far stronger than in most of those he has named in Italy. Any student in the historical seminary at Harvard will tell him that the theological pressure at the University of Padua was, as a rule, nothing in comparison with that at the University of Ingolstadt.

At the centres of Italian thought, whenever there was some local power strong enough to hold the ecclesiastical authority in check, we have such researches as those of Sarpi in physiology at Venice; of Galileo in astronomy at Padua, Pisa and Florence; and of De Dominis in physics at Venice and elsewhere.

And now let me make one concluding remark in reference to Professor Dwight's attempt to arouse sectarian hatred by conveying the idea that I am animated by hostility to the Roman Catholic Church. Nothing can be more contrary to fact. During the twenty years in which the historical evolution of various sciences has been the favorite study of my leisure hours, I have sought to find and to state, simply THE TRUTH. So far from feeling hostility toward the church of which the professor is a member, I have omitted no opportunity to show the good side of its work. I have brought out from its annals every emulating example I could find in its dealings with science; I have dwelt at length upon its beneficent agency in establishing hospitals; I have shown how many monks, despite theological opposition, did much to advance medicine and surgery; I have, while showing the evil results of theological opposition to vaccination, held up the Catholic clergy of Montreal to admiration for their conduct in the ship-fever period; I have done the same thing regarding the heroic conduct of Bishop Belzunce during the plague at Marseilles; I have rendered all honor to Cardinal Wiseman for his attitude in favor of scientific geology, as against Protestant fanatics like Dean Cockburn and Mellor Browne; I have called especial attention to the brave and Christian conduct of Pope Clement VI. in endeavoring to ward off

popular fanaticism throughout Europe from the Jews, and have, more than once, even at the risk of provoking Protestant hostility, called attention to the far better excuse for persecution by the Roman Catholic Church than any which can be put forth for persecutions by Protestantism.

True, I have never warped history; not even to "save souls." My belief is that the first thing for any man to do, is to make his soul worth saving, and that the next thing is to have faith that all souls worth saving will be saved.

It would be strange indeed if one seeking to develop the history of nearly a score of sciences, who makes no claim to be a *specialist* in any of them, should not here and there fall into error. Fair criticism, therefore, no matter how severe, by specialists or others, which shall enable me to rectify my text in the minutest point, I welcome heartily; and my greatest disappointment in this whole correspondence has been to find that Professor Dwight, after all the noisy proclamations of his preface, has shown neither any such familiarity with the history of his own science, nor any such power of reasoning upon what he does know, as will warrant me in accepting him as a competent critic.

I am, sir, very truly yours,

ANDREW D. WHITE.

# RECORD OF MORTALITY FOR THE WEEK ENDING SATURDAY, AUGUST 8, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Infectious diseases.	Consumption.	Diarrhœal diseases.	Scarlet fever.	Diphtheria and croup.

ening; N., snow. \* Indicates trace of rainfall.  $\frac{1}{2}$ — Mean for week.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 8, 1891, TO AUGUST 14, 1891.

Assistant Surgeon THEODORE F. DEWITT, U. S. A., granted sick leave of absence for thirty days.

Captain JOHN O. SKINNER, assistant surgeon, assigned to duty at Fort Clark, Tex.

Major ALFRED C. GIBARD, surgeon, U. S. A., relieved from duty at Fort Niagara, N. Y., and ordered to Fort Sheridan, Ill., for duty.

# OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 15, 1891.

J. BAKER, passed assistant surgeon, detached from U. S. S. "Felix," and authorized to delay reporting in the United States for six months.

J. S. SAYLER, passed assistant surgeon, detached from the U. S. S. "Ranger," and ordered to the U. S. S. "Felix."

V. C. B. MEANS, passed assistant surgeon, ordered to the New York Naval Hospital, September 1st.

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING AUGUST 8, 1891.

PERVIANCO, GEORGE, surgeon. Detailed as chairman Board of Examiners. August 8, 1891.

SAWELLE, H. W., surgeon. To proceed to Portland, Me., for special duty. August 3, 1891.

GODFREY, JOHN, surgeon. To represent the service at seventh International Congress of Hygiene and Demography, July 25, 1891. Detailed as member Board of Examiners. August 8, 1891.

LEWIS, FAIRLAX, surgeon. Detailed as recorder Board of Examiners. August 8, 1891.

MILNE, F. W., surgeon. Granted leave of absence for thirty days. July 20, 1891.

CARLE, H. R., passed assistant surgeon. Granted leave of absence for thirty days. August 8, 1891.

CARMICHAEL, D. A., passed assistant surgeon. Granted leave of absence for thirty days. August 3, 1891.

PETER, W. J., passed assistant surgeon. To proceed to Wilmington, N. C., for temporary duty. July 31, 1891.

PERRY, J. C., assistant surgeon. Granted leave of absence for twenty days. July 28, 1891.

# EXAMINATION OF CANDIDATES FOR MARINE HOSPITAL SERVICE.

WASHINGTON, D. C., August 12, 1891.

A board of surgeons for the examination of candidates for admission into the Marine Hospital Service will be convened at the United States Marine Hospital, St. Louis, Mo., October 12, 1891.

Candidates for examination should make application to the Surgeon-General, United States Marine-Hospital Service, Washington, D. C., as early as practicable, and should enclose testimonials from at least two reputable citizens, preferably physicians, as to their professional and moral character. No person will be considered eligible for examination whose age is less than twenty-one, or more than thirty years, or who suffers from any physical defect which would be liable to impair his efficiency or incapacitate him from duty. The candidate must be a graduate of a medical college of good standing, as evidence of which his diploma should be submitted to the board.

WALTER WYMAN, *Superintending Surgeon-General, M. H. S.*

# DEATHS.

THOMAS L. SMITH, M.D., U. S. N., died at Brooklyn, August 14th, at the age of ninety-one years. For more than forty years Dr. Smith did active service in the medical corps of the United States Navy. He was born in Orange, N. J., in 1800, and graduated in 1822 from the College of Physicians and Surgeons, New York. On March 28, 1828, he received the commission of Surgeon's Mate (now called Assistant Surgeon) from President John Quincy Adams, and began his naval career in the frigate *Hudson* in 1830, going to Brazil. In 1837 President Andrew Jackson gave Dr. Smith the commission of Surgeon. From 1847 to 1849 he was the Surgeon of the New York Navy Yard. In 1850 he went to China on the *Saratoga*, and was made the Fleet Surgeon of Commodore Perry's Japan expedition. In 1854 he was again in the New York Navy Yard, and remained there for four years. In 1859 he was Fleet Surgeon under Commodore Inman of the African squadron. He spent two years in the Mediterranean, and returned home to take charge of the New York Naval Hospital, a position which he held until 1865. During the years 1869 and 1870 he was for the third time in the navy yard, and in 1871 was retired with the commission of Medical Director with the relative rank of Commodore.

WILLIAM COGSWELL, M.D., M.M.S. Præses, died in Bradford, August 15th, aged seventy-two. He was born at Atkinson, N. H., and graduated from Dartmouth College Medical School. He began the practice of medicine at Georgetown, Mass., in 1845, and six years later moved to Bradford. He was President of the Massachusetts Medical Society in 1876, and later President of the Essex North District Society. He was a Member of the Governor's Council in 1877. He was also President of the Atkinson Academy Association and a Trustee of the Haverhill Hospital at the time of his death. He was twice appointed Medical Examiner. He served in the war as Regimental Surgeon.

JOHN J. COCHRAN, M.D., Assistant Surgeon U. S. A., died at St. Luke's Hospital, New York City, N. Y., August 6, 1891.

ANDREW M. MILLS, M.D., of Newark, N. J., died August 11th, aged fifty-five.

# BOOKS AND PAMPHLETS RECEIVED.

Transactions of the Medical Society of the State of California, Session of 1891.

Rescorcin as an Antipyretic. By W. Carroll Chapman, M.D., of Louisville, Ky.

The Influence of Diet on the Growth of Hair. By E. D. Mapother, M.D. Reprint. 1891.

Practical Intestinal Surgery. By Fred. B. Robinson, B.S., M.D. Vol. II. Detroit: George S. Davis. 1891.

Tenth Annual Annoucement and Catalogue of the Women's Medical College of Baltimore for the Session 1891-92.

The University Marine Biological Association. Laboratories and Aquarium Located at Sea Isle City, N. J. Philadelphia. 1891.

A Clinical Report on Intravenous Saline Infusion in the Wards of the New Orleans Charity Hospital, from June, 1888, to June, 1891. By Rudolph Matas, M.D. Reprint. 1891.

Fifty-first Annual Annoucement and Catalogue of the Missouri Medical College, and Tenth Annual Annoucement of the St. Louis Post-Graduate School of Medicine. Session of 1891-92.

The Pocket Anatomist. Founded upon Gray. By C. Henri Leonard, A.M., M.D. Fourteenth revised edition, containing Dissection Hints and Vascular Anatomy. Detroit: The Illustrated Medical Journal Co. 1891.

Stories of a Country Doctor. By Willis P. King, M.D., Assistant Chief Surgeon of the Missouri Pacific Railway Co., Lecturer on Orthopedic Surgery and Clinical Surgery in the University Medical College of Kansas City, etc. With illustrations by T. A. Fitzgerald. Second edition. Philadelphia: A. L. Hummel, M.D. 1891.

## Lecture.

### NEURASTHENIA AND ITS MENTAL SYMPTOMS.<sup>1</sup>

THE SHATTUCK LECTURE FOR 1891.

BY EDWARD COWLES, M.D., SOMERVILLE.

(Concluded from No. 8, page 186.)

*Nutrition*, as the main element of the process of repair, demands careful attention. All the food should be given that the digestive powers will bear, it being remembered that they are weakened with the other functions. Easily digested articles may be required for a time, but avoid slops if the patient can possibly take solid food. Ignore a little dyspepsia as not always requiring drugs; it will disappear as the patient gains in strength. Milk, fish, eggs, vegetables, fruit in abundance, and farinaceous articles, are the main reliance, noting any special difficulty there may be in the digestion of starchy foods.

A variety of plain meats is not contraindicated, except that nitrogenous articles should be limited in the treatment of uric acidemia. Haig mentions that Lange successfully treated certain conditions of periodical depression from this cause, by a diminution of meat foods, etc.; and Broadbent used the milk diet with success in the frequent association of mental depression with high tension of the pulse. Sugar and starch must sometimes be avoided; give cream, malt, etc., and good butter may be freely used, when increase of weight is indicated; weigh the patient regularly, every month at least. A tablespoonful of malt and the same of whiskey or rum, in milk, is a good addition to the light meal that must be taken when there is much acid dyspepsia. One-half drachm doses of aromatic spirits of ammonia, at each meal, are useful in this condition.

Give soups, and prescribe water for its value in nutritional processes, as well as a diluent and diuretic. Milk, eggs, good beef tea, porridges of Mellin's Food, with the addition of peptonized beef-powder, etc., afford a variety for luncheons between meals, and at bed-time. In the long interval between this and breakfast, especially when the patient is wakeful by night, a glass of milk or the like, and better if warmed, is most useful in anticipation of the morning tire. The significant symptom of neurasthenia is an important index also for general treatment. For this condition, give on awaking a glass of warm beef tea, or of milk, with a spoonful of whiskey or rum, and it will lessen the "misery." As a rule, however, stimulants should be but little used. In the weaker cases, with much dyspeptic disorder, the regular milk diet, as much as can be borne, and frequent feeding, may be employed along with the "rest-treatment." At the beginning of the treatment, a precise plan of dieting should be written out, with the prescription for each of the fixed hours for meals. Require the nurse, if there is one, to keep an exact record of what is taken, along with the clinical chart and other notes.

*Rest*, as a prime requisite, should be at first absolute and continuous, or partial. The first is appropriate when there is general exhaustion, or conditions of body that admit of it as an aid in improving the general nutrition for the relief of local neurasthenia.

It is contraindicated in the graver degrees of depression, and especially of irritable restlessness and agitation. Then it must be modified, and some degree of partial rest may be employed. The point is to get as much rest as possible for the patient, until he has acquired some storage of energy, to permit of its use within physiological limits, and to relieve the distressing sensations that are the basis of the lowered emotional tone. Get all the rest possible without increasing the irritation. In some cases the regulation time of six weeks is enough for the absolute rest; sometimes many months of partial rest are required. There seems to be no rule except careful trial. In the bed-cases the time seems to be indicated by a positive gain in weight and improved quietude in feeling; then it may be necessary that exercise should be urged upon the patient.

*Exercise*, properly regulated, is essential; it should be begun gently and increased gradually, in all cases; in the severer ones the patients may get up first in the afternoon, then after a time, in the forenoon, but should be kept in bed till after breakfast for a long time. Get them out of doors daily for fresh air and moderate exercise. This is the plan for partial rest to which cases of pronounced depression and restlessness should be subjected as far as practicable. When the irritability is great, permit them to get up occasionally, to lie on a couch, etc., but promote resting in any way it can be gained. *Exercise should always be kept within the limits of fatigue.—this is the golden rule of neurasthenia.* Macfarlane well says that fatigue invariably intensifies the symptoms, whatever the limit may be; and this must be determined for every individual case.

The guides to the limit of fatigue are most obscure. It has been seen that the feeling of it does not measure it in the well, and that in the weak, one of the most important facts in the disorders of the "sense of body" is what may be called anæsthesia of the sense of fatigue. There is no escape from the logic of this condition,—the patient's appreciation of it must always be interpreted by the physician, who must also study all the signs of fatigue, and direct the patient as to the kind and amount of exercise. The effect of this, upon pulse and temperature, for example, should be watched. When the temperature is sub-normal, the conditions of elimination, nutrition and rest should be carefully maintained. Then, even a little exercise often seems to increase the irritability; but when the temperature becomes normal, more exercise can usually be borne without this effect, in the more acute stages of neurasthenia. In cases of long standing or partial recovery, of the irritable and ambitious or conscientious type, great depression and a sense of "terrible exhaustion" may follow as a reaction from indiscretion in exercise; this may be prompted by a period of comfort when the sense of fatigue may have been quite reliable as a guide within the narrow limits of much repose and gentle effort, but it is quickly lost under a little stimulation or excitement. Such a patient may astonish and mystify all concerned by extraordinary displays of apparent endurance, but it has to be "paid for" with the repentance that comes with the exhausting reaction that may amount to a true relapse. These effects not being appreciated by the patient as simple signs of fatigue, the "repentance" is quite sure to take the form of renewed and intensified self-reproach, with all its harmful effects.

<sup>1</sup> Delivered before the Massachusetts Medical Society, June 9, 1891.

The careful prescription of exercise is one of the most important duties of the physician in these cases. Within due limits it increases vigor by the law of physiological use. It quickens digestive processes and excites the appetite, and promotes sleep. He must "follow up" his patient and protect him in this particular, until he has acquired a sufficient reserve of energy, and a sufficiently normal "sense of body" to be his own guide. If the physician does not do this he will surely let his patient suffer painful relapses which too often occur in spite of all advice. For patients having cerebral exhaustion, though bodily well nourished, and with effects of sedentary habits, exercise should be coupled with efficient elimination, but it should be remembered that there is also increased central fatigue with all voluntary muscular effort. This must be carefully limited at first, in these as in other cases, while reasonable entertainment is a necessity.

*Massage* counteracts the tendency to enfeeblement from long rest,—it affords exercise without the expenditure of energy by the patient,—it promotes the removal of the toxic and waste materials from the tissues, and their healthy nutrition. It must be managed with care and not be too long-continued, but may be followed by medical or general gymnastics of the gentler kinds, or other voluntary muscular exertion, to the extent to which the patient bears it without aggravation of the neurasthenic symptoms. Electrical treatment has been much commended both for its sedative and stimulant effects, in the forms of central galvanization or general faradization; the functions generally improve under its tonic influence. It may be employed for a few weeks every other day. It often has a mental effect.

*Sleep* should be promoted with as little use of hypnotics as possible. They tend to spoil the appetite and to produce secondary effects. Toxic quietude of brain cells may not promote their rest and nutrition. In the diverse causation of neurasthenia the conditions inducing insomnia are varied. Its cause should be determined, in each case, as nearly as possible. There may be some special toxic influence, errors of diet, too much mental work and too little bodily exercise, the rheumatic or gouty diathesis, etc. While the blood tension is usually low in anæmic conditions, it is again high, and a few minute doses of calomel at night with alkalis during the day, are indicated. Sleeplessness from physical over-fatigue may be relieved by the wet pack, a warm bath, or massage, with some liquid nourishment in moderate quantity. — with a little wine or brandy and a biscuit.<sup>61</sup> If the patient must have something for a hypnotic, do the least harm possible. In such cases Folsom<sup>62</sup> uses preferably an unpleasant drug, — a few minims of paraldehyde in a drachm of chloroform water, and this can be repeated a number of times. This drug is a safe one in drachm doses, when it can be taken; and a second dose may be given after two or three hours; peppermint water is a good vehicle for it. Sulfonal is, at present, to be regarded as one of the safest hypnotics. Begin with ten or fifteen grains, and when its cumulative effect is gained, reduce it to ten or seven grains; it should be pulverized and given in a moistened spoon, one and one-half hours before its effect is expected. Phencetone, five or ten grains, two or three times daily, is sometimes a

good adjuvant when there is nervous distress and restlessness; or it may be repeated every hour, or half hour, till twenty or thirty grains are given, for the relief of pain. Warm baths and night feeding are very effective in the long run. Most patients who lie much in bed can get on with comparatively little sleep. It is better to go without as much as is desired, or wait for it to come, rather than to create a drug habit. Two or three hours each night will do very well for a considerable time in such cases. Beware of using the bromides and chloral continuously. Patients are sometimes brought to the asylums in toxic conditions from these drugs or from paraldehyde. The first may be given moderately for a short time only, — not more than one week. Iron and other tonics that improve the appetite may be given when well borne. Aromatic spirits of ammonia in half-drachm doses may be used frequently and safely in paroxysmal nervousness.

The *subjective* and mental symptoms, in relation to treatment, demand the special attention that their importance in diagnosis indicates. In studying the objective symptoms, a general though brief review was made of the measures ordinarily regarded as therapeutic. This included not only the physical signs, but necessarily also that group of coincident subjective indications of which we can only know by what the patient says of his bodily condition; his appreciation of it may be mainly correct and corroborative of the physician's observations, or be interpreted as consistent with them. This includes the *inward* reactions, or *negative* symptoms of the physical disorder, according to Putnam,<sup>63</sup> distinguishing them from the *positive* or objective signs.

But we have seen how the normally correct appreciation of the "sense of body" is qualified in the well; and how with the onset and increase of pathological "fatigue" there is an increasing impairment of appreciation, requiring interpretation by the physician. We have seen also how the impaired and altered "sense of body," and special senses as well, in respect to the group of subjective symptoms just mentioned, affect the strictly mental indications. All can agree as to the symptoms of neurasthenia being mainly subjective; and as to the fundamental facts of irritability and languor in mind and body, — and of mental depression and weakened control. Our study of the mechanism of these alterations of mental activity leads us to see clearly the significance of such effects, and that "the higher mental states are the sensitive indices of the lower physical changes," affording us the truest guides to diagnosis and the need of treatment.

The subjective symptoms, with a correct interpretation of mental states, are the chief guides to diagnosis and treatment. They give the earlier and finer indications, for they always exist when there is neurasthenia; they are often present, and complained of, when there are no clear objective signs. The paramount importance of the mental condition becomes plain because it has to be treated from first to last; there is often no guide but this. Even when all objective signs have for some time disappeared, there can be no assurance of recovery until the patient can say that there is permanent freedom from the depression, irritability, or languor of feeling, and that he has acquired the power to control his own mind, and his natural force is not abated. The most critical periods of the

<sup>63</sup> J. J. Putnam. Art. Neurasthenia, Ref. Handb. of Med. Sc.

progress towards recovery, when the danger of relapse is greatest, are when the only guides to the limits of fatigue are the subjective and mental symptoms,—what the patient feels and thinks as to his own condition. But that itself does not guide,—it is continually leading astray the patient and often the physician. The true guide is to know what it is that makes the patient feel and think as he does. It is upon the correct interpretation of the mental signs that successful treatment largely depends.

A correct knowledge of the working of the mental elements is essential to put the physician into a proper and controlling relation to the case. The very first indication for treatment is that the confidence of the patient should be gained as soon as possible. This is aided by the careful examination, that should always be made, in every particular, bodily and mental, that is needed to establish the diagnosis. It is then important to give the patient a clear understanding of the nature of the malady. Intelligent patients are always very ready to accept correct explanations of their condition and experiences, and it is often most satisfactory to them to know, for example, the reason for the morning tire, and to understand the principle of anaesthesia of the sense of fatigue. They know what it is to be too tired to feel fatigued. The first thing is, therefore, to know what is the matter, and then to get the patient to know it; this gains the willing and intelligent co-operation of the invalid,—relieves greatly the worry,—and thus directly promotes repose and the arrest of exhausting processes both in body and mind. All writers agree as to the importance of gaining such co-operation, and advise careful attention to this part of the treatment of such cases.

When the physician thus appeals to the understanding and interest of his patient, he addresses himself exactly to the moulding of the mental elements that are involved in the malady,—he sets himself, at the outset, to treat the symptoms that all observers note as among the earliest to appear. The first clinical procedure, then, with which the treatment is begun, is to get the whole story of the patient's experiences with reference to the symptoms, as soon as practicable. When neurasthenic patients come to the physician they have usually made a number of attempts at "resting," and have suffered as many relapses because the golden rule of keeping within the limits of fatigue was not followed to the completion of convalescence. The patient comes because he has begun to think that something serious is the matter, and that because recovery does not come it may never come.

The treatment of neurasthenia, with respect to the indications given by the mental elements, resolves itself into procedures suited to two general groups of indications. These may be broadly distinguished as the *first-effects* and the *after-effects* of the neurasthenic condition. Among the first-effects, or those attendant upon the active operation of the neurasthenic influences, are the direct and immediate results of excessive expenditure of energy, deficient repair, toxic effects, etc.; these may represent the formative stages of the supposed "molecular or chemical variation" that is manifested as "an exhausted or changed nutritional power." Among the after-effects these changed conditions become more pronounced; the expenditure of energy may be greatly lessened, but it is limited by its relation to weakened assimilation; the toxic elements may have been largely eliminated, though some of their

effects remain; the condition is more strictly one of "irritable weakness," and all the secondary effects of morbid habit and association are in full force. The neurasthenic condition, as modified by after-effects, presents a materially different problem as to mental treatment.

In the early and active stage of neurasthenia the problem is a relatively simple one for the analysis and interpretation of the mental symptoms as a guide to treatment. The history of the case should make it easy to distinguish the four orders of the subjective symptoms, and to trace their development. Take for example the case of the physician whose account of it was quoted, in a previous page, from his letter. At the closing of a busy year, while still doing very active work, he felt that it required greater effort; he could not help worrying unduly; there were threatenings of the sciatica to which he had been most subject at that time in the year, and he sometimes felt considerably fatigued. After three weeks of greatly lessened work, the four orders of symptoms were more plainly revealed; there was (1) "a letting down of spirits;" (2) lessened control over his worry; (3) the worry was consequently increased, and there was (4) an altered "sense of body," shown in nervous irritability and languor, and excessive sense of fatigue. The condition being further interpreted, there was more real "fatigue," but it was concealed by a fatigue-anaesthesia when he was still active, than later when he felt it more keenly after partial rest. In other words, he was really better when he felt worse,—he was recovering his sense of fatigue. This was proved by the sequel: in the fourth week, with no change in affairs, etc., and no treatment other than the comparative rest, he was quite well, was changed in appearance, had recovered his cheerfulness, and began his summer vacation with better zest than for a long time before.

In another case, a lady engaged in clerical work had for three months an increasing tendency to aching and a sense of pressure in the head, and to waking early in the morning; she would not confess to morning "tire," but said she felt "worse" then; she worried, felt the need of greater effort to begin her daily task, but "*could work faster*" than before, and being conscious of not feeling well, she expected a short vacation to restore her strength. On returning to duty, the work seemed very difficult and not half done on the first day, and impossible the next, from weakened mental control; the insomnia, worry, etc., greatly increased, and a prolonged rest with careful treatment had to be ordered. She knew she was "running down," by failing appetite and loss of weight. Otherwise, there was little in either of these persons besides the subjective symptoms to call attention to the neurasthenic condition; neither was it appreciated by them until there was lessened stimulation by work to be done. The four orders of symptoms were plainly shown in the last case; their earlier recognition would have clearly guided treatment obviously necessary to have saved the patient from so dangerous an approach to a serious mental breakdown. This applies particularly to the fourth order of symptoms,—to the fatigue-anaesthesia, and the deceptive facility from irritable weakness, that enabled the patient to "work faster," thus increasing her danger. In the more advanced cases, the mental indications, as first effects, are clearer, and their analysis easier. Their value as guides to treatment is more readily apparent, pointing to their

origin in organic inanition and auto-intoxication as the double cause of the "fatigue."

The after-effects of the neurasthenic condition present modifying indications that have to be met in the plan of treatment. These are seen in the latter stages, either in convalescence or chronicity. The significance of the symptoms, in this regard, has been pointed out. For example, one who has regained some reserve of nervous energy, and maintains a fair degree of comfort when effort is kept within his limits of fatigue, may be prompted by desire, or a sense of duty, to over-exertion. The undue quickness of response to the stimulation of interest and attention is to be recognized as an evidence of the irritability of unstable weakness. The apparent ease and zest of the effort is not due to real power, but there is a speedy blunting of the sense of fatigue. The reaction of exhaustion and mental misery that come as after-effects are not to be interpreted as the patient feels and thinks, but as precise manifestations of — (1) changed organic sensations shown in a lower emotional tone and "hopelessness," — (2) the decrease of the mental power of control in weakened attention, — (3) worry, self-reproach, and apprehension as simply signs of a relapse of the "fatigue," the limits of which were exceeded in breaking the rule of treatment. The fundamental weakness is shown, from the beginning of the event, in (1) the susceptibility to stimulation and quickly changed sensations, followed by increased exhaustion and irritability.

Such an analysis of a later stage of neurasthenia reveals the four orders of symptoms as we may observe them in a case under proper treatment, in which there may be a measurably effective elimination, but defective assimilation still remaining, and therefore prolonged inanition. The irritable weakness is more characteristic, and the indications for treatment are all the more significant. The whole matter comes, in time, to this: — the condition is one of deficiency of nervous energy, — the problem is to effect a re-storage of that energy. It is a part of the process that the power to do things can only be maintained or regained by the doing of them, — by the law of use and disuse. But the patient must always be "kept within the limits of fatigue" during treatment, through convalescence, to establish recovery.

In these later conditions the advantage of intelligent co-operation on the part of the patient becomes more evident. It is a part of the treatment, therefore, that the patient should be taught to make a correct interpretation of his symptoms; he will thus become an aid to the physician, and learn finally to be his own guide as to the limitation of effort. One cannot "go by feeling" whose power to feel is itself disordered, and this lesson once learned has a therapeutic value by leading the patient to "go by judgment." But it is precisely because of weakened attention and morbidly intensified feeling that the better and often accepted judgment cannot be held. Here comes in one of the chief duties of the physician with respect to the patient's mental condition. It has been seen that his "exercise" must be followed and guided with persistent care. As the changes in bodily conditions are best revealed by the mental indications, the physician should be followed with sufficiently close observation, and encouraging counsel, to enable the patient to hold to the way of recovery and to faith in the necessary means. It is a part of the physician's business to repeatedly uplift his patient

by explaining the newly-arising worries, and directing as to diet and exercise. If he is left to himself too early in regard to all these matters, relapses are very sure to come through inability to interpret correctly the altered sensations and the fallacious appearances of returning strength.

The foregoing considerations apply particularly to the large class of patients that have to be systematically "held back" in all stages of the neurasthenic conditions. The opposite class of cases has been mentioned that require urging to effort, when the proper time comes. Here is revealed more plainly another modification, as an after-effect, that always introduces great difficulty into the treatment. It is the effect of the laws of use and disuse, — of practice, habit and association. The long continuance of disordered activity has created a "functional disposition to repeat organic processes" in a morbid way, and it has been shown how this involves a like association of morbid ideas and feelings.

The "functional disposition" may work to good or bad results. In either case the principle is the same, — the law of use and practice rules. To overcome a harmful "disposition" to repeat organic and mental processes is exactly to re-acquire good habits by the practice of them. Hence it is that the power to do things comes by doing them, and by gradually gaining the effects of practice. Small beginnings are necessary in these cases of neurasthenia. It is the persistence of repetition that is efficient. In the condition of first-effects there is lack of power, and it is plain that there is no place for heroic methods of breaking up morbid "dispositions" and habits. More harm than good is likely to be done by dominating methods unless based upon a clear insight. But forceful measures may sometimes be wisely used; it is only when power is sufficiently restored that such measures are justifiable as against morbid habit in the "after-effects." Confidence gained, and the truth made plain, are the best helps. In the peculiar cases requiring it the best way is for the physician to suggest in advance the new effort to be made, "not now, but by and by," when the patient is going to be ready for it. He becomes familiar with the idea, and when the time comes the expected effort is successfully made. This is leading along by holding back; such patients are afraid of being "pushed;" they have usually, in the earlier stages of the malady, made mistakes in "pushing" themselves or by having it done by others. The patient's mind should always be prepared in advance for changes. Much is gained by giving the confident expectation of recovery. This is one of the best remedies of all, and it can be truthfully applied because most cases of true neurasthenia should get well.

The rule has been laid down that "exercise should always be kept within the limits of fatigue," and we know that the guides to those limits are most obscure. It is equally the responsible task of the physician not to overdo his duty, in the cases that have to be held back, and in those that have to be urged to effort. It is precisely in the extreme cases of the latter class, — what Mitchell would call the "vampire" type, — that the greatest discretion must be used. Such patients are often the victims of morbid-association habit and a self-indulgent egoism; under the spur of a seemingly perverse interest, they will sometimes make unwonted and extraordinary effort. We must realize that this may be done without a concurrent sense of fatigue,

which may come later in a real and most painful way. Then the patient has a new argument to sustain her self-deception that all effort is bad; and even the physician is sometimes put at fault if his heroic measures are not successful. There is need of sympathetic helpfulness even here.

We often ask ourselves, in all cases requiring enforced effort, what are the "limits of fatigue"? It is perhaps the clearest guide in such cases that "exercise" may be pressed with safety while the fatigue of it is *felt*, even sometimes to the degree of painful *tire*. To avoid "fatigue" is to keep within the limits of *pathological* fatigue, which gives due warning by the signs of fatigue-anæsthesia. This rule applies as well to the graver cases of neurasthenia presenting mental symptoms, when the progress upward toward recovery reaches the degree where normal fatigue is felt. In such cases, after the symptom has been left behind that technically differentiates melancholia, it is neurasthenia the rest of the way to health.

A change from the usual surroundings often does great good. The breaking up of painful associations, on the principle of "out of sight, out of mind," always holds good to some degree. Even homesickness is often salutary,—it is a natural and wholesome "worry" that works to advantage when it displaces a morbid worry. Dependence upon devoted and sometimes over-sympathetic relatives is likely to endanger the formation of degenerative habits in long and severe cases.

It has often been said that the very first requisite for successful treatment is to gain the confidence of the patient; this recognizes the leading importance of the mental element. It is a part of this requisite, however, that the physician should first earn the confidence he seeks to gain. It is the *interest* the patient has in the means for cure that is the most helpful motive; and we have seen what control a feeling of interest has over the attention. But the patient's interest is very exactly measured by what he feels is the physician's interest. This means sympathy,—for that and such interest are one. The physician's sympathy must be genuine,—no one more quickly than such a patient detects a false tone in it. No one more readily sees the fitness of good explanations. But the way to true sympathy is plain,—it springs from knowledge. The physician should first know his case,—then all that is needful follows. No good physician, who acquaints himself with the marvellous simplicity that underlies and rules the elements of his patient's suffering, and thus sees the way to cure, but must be keenly alive to the worthiness of the most skilful efforts. The patient's interest will then take care of itself,—his attention is held through motive interest. In mental matters all this is strictly physiological, which Bucknill says is true of all that is meant by "moral treatment."

**Conclusion.**—The purpose of this study of neurasthenia is to contribute something in the search for the philosophy of its treatment. To make this philosophy practical, it must be drawn down to plain terms. We have seen that the central fundamental fact is nervous weakness, manifested primarily in two ways: (1) by an exactly parallel weakness of mental inhibitory control through voluntary attention, and (2) by the central motive element of a lowered emotional tone, from a sense of ill-being. The first of these indications may be concealed, even from the patient himself, by

intensified interest and increase of effort; the second he *feels* and soon betrays.

The complex accessory conditions of changes in the sensations,—irritability and hyperæsthesia, languor and anæsthesia, and their causes,—have been explained. These are manifested a little later than the primary mental effects. The prime indices of the neurasthenic condition, therefore, are weakened mental control and a painfully intensified motive element. It is this central emotional tone, determining *interest*, that has the sway; this is our point of attack. There are two ways of approach to it: (1) through the body, restoring its strength and well-being,—mental comfort and control follow; (2) through attracted attention and suggested ideas we reach the emotional tone,—healthful feeling and interest attend upon wholesome ideas.

While the patient is in the condition of first-effects, as long as the causes of bodily ill-feeling persist, we can only palliate, or prevent increase of trouble,—only transient effects are produced by influencing the emotional tone in the second way. Here the chief aim is physical restoration; this being soon accomplished, all is well. We prescribe rest and urge nutrition; this means also elimination. But in the condition of after-effects, the problem is changed. The toxicity of true neurasthenia being removed, and that of special diatheses, as of uric acid, being controlled, we have to deal with inanition from cell inaction, and the effects of habit. The patient finds it easiest and most *interesting* to attend to the habitual association of morbid ideas and feelings. The body in repose is then comparatively comfortable, while there is only a weak tolerance of a little effort and toxicity; the way to the motive element for the stimulation of healthful *interest* is through ideas. But effort is painful, the will is weak, habit is strong. Hence we instruct our patient how to understand his contradictory symptoms; we introduce corrective factors into his mental equations, raise or reduce others to their true powers, and eliminate the constants of error. Then we prescribe exercise, urge practice within the limits of fatigue, and maintain elimination and nutrition. By physiological use, the will recovers its power, exercise promotes assimilation and elimination, and increased vigor; effort becomes easy, wholesome interests revive, and the emotional tone is one of ease and comfort.

The maintenance of a sense of well-being, under reasonable effort of body and mind, is the sign of obedience to the rule that "exercise should always be kept within the limits of fatigue." Normal fatigue is simply wholesome *tire*,—then rest is welcome and is followed by immediate comfort. Pathological fatigue is attended by fatigue-anæsthesia, and this marks the beginning of danger. We find our natural safeguard against that danger in observing the mental effects that quickly manifest their close relation to normal fatigue and its toxic products. But we have seen that when wholesome tire passes over into pathological fatigue, there comes over-tire not only to the central and motor, but to the sensory, elements of the mechanism. The recognition of the mental effects of the changes in the "sense of body" is our constant guide to prophylaxis and treatment,—for both of these uses, the golden rule is that exercise should always be kept within the limits of *pathological* fatigue. Fatigue-anæsthesia betrays us into its toils,—it is a danger-signal if we recognize its significance.

were made to these experiments at the time; but, to my mind, the only important one from our point of view is that nearly all the animals were put on food which was not suitable for them. The carnivora in John's list are 60 pigs, 20 dogs, and nine cats. The dogs and cats I have not been able to trace to the original sources, but it is worthy of note that Wesener classes the cats as all negative. Pigs give the best result, it making no difference if the food is cooked or not, which strongly suggests error. Sauer's<sup>11</sup> note, that the animals in a zoological garden were fed for years on tuberculous meat, without contracting the disease, is of interest in this connection.

To return to the state of affairs with men, law and custom combine to reject the whole of highly tuberculous, emaciated cattle, but allows the sale of flesh from animals with localized tuberculosis, if in good condition. What danger do we incur by eating this meat? Many are calling for the total condemnation of all tuberculous cattle. There are very few, if any, records of tuberculosis in normal muscle, which will stand criticism. The danger, therefore, is confined to the germs which may have slipped into the general circulation shortly before death. To determine this danger, many experiments have been made by inoculating the juice pressed from the flesh of highly tuberculous cattle into rabbits and guinea-pigs. I have collected from Arloing,<sup>12</sup> Dreschfield,<sup>13</sup> Galtier,<sup>14</sup> Kastner,<sup>15</sup> and Nocard,<sup>16</sup> the tests of fifty-nine cattle, with 13 positive results, all from highly affected animals. Besides, there are Steinheil's<sup>17</sup> experiments with the flesh of people dead of phthisis, with nine trials and some positive results. As dead cattle are not allowed in the market, these results do not apply. Also, Bollinger states that Kastner has recently made five tests with condemned flesh, all positive, and one with flesh from a highly tuberculous but not condemned case, with negative results.

From the above we are justified in concluding that tubercle bacilli, in meat as sold under inspection, are rare. What effect, if any, the long keeping of the meat before eating has upon the bacillus, is not known. This should be inquired into, since muscles become acid on coagulation, and acids have a distinctly deleterious effect upon tubercle bacilli. The mass of our meat is cooked before being eaten, and in this way what danger there is, is greatly reduced. This is shown at once by the experiments on animals (all negative), and the fact that heat, such as that applied to ordinarily cooked meat, is sufficient to kill the bacilli.

The results of feeding man with tuberculous meat, reported by Schottelius,<sup>18</sup> are of interest. The people about Wurzburg, believing such meat to be harmless, made so much complaint, that its sale, under careful supervision, was allowed during a part of 1868. The carcasses were bought whole, and divided between twelve families. In all, 49 cattle were consumed before the authorities gave up keeping the record. If such food is dangerous to any degree, the result should have been a marked increase in the amount of tuberculosis in the twelve families, as compared with the rest of the population. This was not the case. Up

to the time of report, in 1883, there had not been a case of tuberculosis which could be attributed to the food, though surely seventy people regularly lived on it.

Also, Bollinger<sup>19</sup> cites the town of Ritterwiesen, where there was much tuberculosis among the cattle. Yet, in spite of the general consumption of their flesh and milk by a population of 425, there were only three deaths from tuberculosis during the years 1874-78, inclusive. Curiously enough, none of the three deaths occurred in the families which ate the flesh. The same author inquired into the history of all the founding-families known to consume tuberculous meat, and failed to find a single case of tuberculosis.

To sum up, there is little absolute proof that raw flesh, when consumed in the course of nature, is dangerous. Yet, after making allowances for the inaccuracies of experiments, there is no doubt but that there is some danger. As regards cooked flesh as consumed by man, there is no evidence of danger, though we have many records where bad results might justly be expected were they at all common. I do not mean to oppose inspection, — far from it. All cases of general tuberculosis should be condemned; but I do not believe that the danger justifies the total seizure of all tuberculous cattle. The expense is too great; the same amount of money will produce better results when applied in other ways.

Milk, often consumed raw, and at one time or another an ingredient of the food of every human being, is generally accepted to be a greater source of danger than flesh. It has long been known that the tubercle bacillus is liable to occur in the milk of tuberculous cows; and much time has been spent in an endeavor to gain an exact knowledge of the danger. There are four classes of observations to consider, — feeding experiments, dating back to Villamain; inoculation experiments; direct microscopic study of the milk; and the prevalence and nature of tuberculosis among the consumers of raw milk, chiefly the young.

I have only been able to collect a few of the reports on feeding, since the articles are mostly in out-of-the-way places, and not specially indicated by the titles. They are, as far as possible, briefly summarized.

Gerlach<sup>20</sup> fed the milk from a cow showing marked tuberculosis of the thorax at autopsy (other organs not noted) to a number of animals. These, killed at intervals, showed tuberculosis, more or less general, throughout the body. All the animals received other food than that from the cow. There were no control animals, and no note of precautions taken to avoid other modes of infection.

Schreiber<sup>21</sup> fed three guinea-pigs and 18 rabbits with the milk from a tuberculous cow for some time, results negative.

Bang<sup>22</sup> has fed the milk from five cows with tuberculous udders to pigs and guinea-pigs, with positive results in all.

Cavagnis<sup>23</sup> reports three young guinea-pigs suckled for eight, twelve and thirty-two days by a tuberculous mother, with negative results.

Pench<sup>24</sup> fed 4.470 grammes of milk from a cow with tuberculosis of the udder to a pig. This, killed

fifty-six days later, was found to be normal. (Four rabbits inoculated at the same time developed tuberculosis.)

Ernst<sup>22</sup> has reported the result of feeding 13 calves with the milk from 13 cows supposed to be tuberculous and free from tuberculous disease of the udder. In five of the calves tuberculosis was found; in seven none; and one was suspicious. Only eight of the calves were fed with the milk of one suspected cow; three of these were found tuberculous. In all, six cows were used. Of the three infecting cows, two had disease of the udder. In one no autopsy was made. In all three calves there were tubercles in the liver, and, in one, in the kidney. None were reported in other parts of the body. No control animals were reported.

Besides the above, there are many more, as Wesener, in 1885, gives the figures as 86 animals experimented on, with positive results in the two calves, three-quarters of the pigs, half the sheep and goats, two-fifths of the guinea-pigs, very few of the rabbits and none of the cats. How many animals the milk came from, or the state of the udders, is not given; probably most had trouble in them, as at that time experimenters were working for effects, not relative danger.

These results are not striking, considering the source of the milk, and accepting them as they stand. Probably in most cases the results as given represent the facts; but control animals, less advanced lung trouble and more intestinal trouble, would have made them stronger. Affection of the mesenteric glands, as will be shown later, is not a proof of intestinal infection. It is also unfortunate that pigs fed on boiled milk were affected, for the bacilli in these cases must have come from elsewhere.

There are quite a number of inoculation experiments which are chiefly of value owing to the sensitiveness of the test. They only demonstrate the possibility of danger, and in no way show that the milk would have been injurious if consumed in the ordinary course of affairs.

Hirschberger<sup>26</sup> has experimented with milk taken in the laboratory from the udders of slaughtered cows. An admixture of blood was avoided as much as possible. His results were, with highly tuberculous cows, four among five positive; with middle-grade tuberculosis, four among six positive; and with pulmonary phthisis only, three among nine. All told, eleven positive results in twenty trials. Udders presumed to be normal, but no careful examination made.

Pouch<sup>27</sup> injected 10, 20, 30 and 40 grammes of milk, from a cow with tuberculous mammitis, into four rabbits. All died of tuberculosis.

Noeud<sup>28</sup> has tested the milk from ten cows with advanced tuberculosis, but none of the udder, with negative results throughout.

Martin<sup>29</sup> has tested 43 lots of city milk. He classes the results as three negative, one positive, five doubtful and four discarded. Personally I should discard one, class eleven, as distinctly negative, and the other as doubtful. Tubercle bacilli were not sought for, but bits produced the disease in other guinea-pigs. The trouble very likely was pseudo-tuberculosis; but granting that it was tuberculous, the autopsy does not read

like a case of inoculation into the abdomen. The lesions in the abdomen were fresh; the omentum was free from trouble; and the bronchial glands were enormously enlarged.

Bang<sup>30</sup> experimented with the milk from two cows with advanced tuberculosis but normal udders; results, one positive and one negative. Later, he reported trials from 21 cows with general tuberculosis and no disease of udder, with only two positive results. He also tested the milk from eight phthisical women, with negative results. Later still, he reports the result of another series of 21 cases with 17 negative and four positive results. Of the four positive results, three had tuberculous udders and the other was doubtful.

Stein<sup>31</sup> has inoculated the milk from 14 cows taken, (like Hirschberger), after slaughtering, from the amputated opened udder. In four cases, he claims positive results. In two of these the udder was affected; in one is given as "normal but yellow," that is, not normal; in the fourth no statement is made. Why the third case is classed as positive is difficult to perceive, since the only evidence was some enlarged lymphatics, in which no bacilli could be found. Other similar cases are classed as negative.

Caivano<sup>32</sup> inoculated the milk, mixed with blood, from a tuberculous cow, and got a positive result. The udder is given as apparently healthy.

Ernst<sup>33</sup> got seven positive results by inoculation of milk from 14 cows, udders healthy.

Galtier<sup>34</sup> has reported inoculations from two cows, one with, and one without tuberculosis of the udders. The first gave a positive, the second a negative result.

Taking the figures just as they stand, we have 125 trials with cows' and women's milk, with 32 positive and 93 negative results. Of the positive results eight are given as having tuberculosis of the udder, 23 as not, and one doubtful.

My judgment leads me to reject all cases where the udder was opened after slaughtering. This would reduce the positive results to ten with no tuberculous disease of the udder,—the three of Bang and the seven of Ernst. Bang, in his last notes, evidently inclines to the view that bacilli are at least very rare in milk when the udder is not tuberculous. Of Ernst's seven cows autopsy is lacking in six; four showed some form of disease of the udder; and in the one autopsied this was tuberculous. This alters the figures most strikingly, and reduces as to Bang's three cases, which, as already stated, he does not put much weight on, and three of Ernst's cases without autopsy. It is hardly necessary to call attention to manifest difficulty in proving the absence of tuberculosis in a large organ like the udder.

Searching for the bacillus in milk as a test is not of practical value for our purposes. In milk from ordinary tuberculous cattle, slide after slide must be gone over in the hope of finding a bacillus among a number of other bodies, which, after hours of fatiguing labor, are only too apt to get the better of tired brain and eye. Of the truth of this statement I have seen many a practical demonstration. Even if the plant only occurs where there is disease of the udder, inspection does not give security, as the early diagnosis is very

difficult. But as only a small portion of the tuberculous cows have tuberculous udders, the amount of tuberculous milk would in this case be quite limited.

The occurrence of tuberculosis among calves, infants, and a few other groups of milk-consumers, alone remains to be considered. Since calves are exclusively fed on raw cows' milk, they offer the very best of natural experiments as to the danger of milk. I have collected from various sources<sup>85</sup> the slaughter-house reports of the amount of tuberculosis in calves.

23,557 calves with	2 cases of tuberculosis.
30,477 " "	1 case " "
143,218 " "	35 cases " "
23,592 " "	1 case " "
800,000 " "	5 cases " "
24,766 " "	1 case " "
87,685 " "	26 cases " "
1,133,195	71 = .006%

These figures can be explained in several ways: first, that calves are only infected with difficulty by tubercle bacilli in their food; second, that there are very few bacilli in milk; third, that the disease does not have time to develop before the calves are killed; fourth, that tuberculous cattle do not suckle their calves.

Our evidence as to the first is not extensive, but, so far as I know, calves fed with milk known to be tuberculous have become tuberculous themselves. This is in accord with the condition of the digestive tract and the general law of susceptibility in young animals of all kinds. We are therefore justified in rejecting this proposition.

There is a good deal to be said in favor of the supposition that the disease does not have time to develop before slaughtering. Calves are killed, I am told, chiefly when from four to six weeks old, but the age may be more or less. The time is short. On the other hand, much can also be said against it: first, the calves found tuberculous prove that the disease can be recognized; second, the time is sufficient for the development of the two lesions to be expected from intestinal infection, those of the intestine and of the lymphatics of the mesentery. Again, young cattle, though more affected than calves, offer very few cases of tuberculosis. That tuberculous cows do not feed their young has nothing to support it. They are just the cows most liable to, as it is the poor milk which goes to the calf and the good to the man.

The second proposition, that there are but few bacilli in the milk of most tuberculous cows, is the only one left. This, taken in connection with the fact that the milk from cows with advanced tuberculous udders is so bad as to preclude its use for any purpose, affords a satisfactory solution.

I have reasoned as though all calf tuberculosis was due to food. This is certainly not the case; much is surely due to inhalation.

How about babies? They are the important test. Are many cases of infection from milk recorded? Certainly not, as shown by the difficulty in finding any. I have, however, found the following, and like enough there are as many more.

Leonhardt<sup>86</sup> reports the case of a healthy infant of healthy parents, which was weaned and put on cow's

milk. The child soon died of tuberculosis of the meninges, intestines, and mesenteric glands. The cow which gave the milk was found to be tuberculous. Another child fed from the same cow died, at about the same time, from tubercular meningitis.

Sontag<sup>87</sup> reports the case of a six-months' infant of healthy parents, which at autopsy showed milary tuberculosis of the meninges. It was fed with milk from a tuberculous cow.

Hernsdorf<sup>88</sup> gives three cases in which there was extensive intestinal tuberculosis, besides less of other parts. One had taken uncooked milk from a tuberculous cow. The original not seen, but the reviewer seems to doubt one case at least.

Demme<sup>89</sup> reports the case of a four-months' infant, which at autopsy showed tuberculosis of mesenteric glands; bacilli were found, but none elsewhere, in spite of great care. There was no tuberculosis in the family for two generations on either side. The milk came from a cow with general tuberculosis. Microscopic examination of the milk pressed from the depth of the udder gave a positive result after examining twenty to thirty cover-glasses, — not clear, but milk apparently taken from the udder at autopsy.

Bollinger<sup>90</sup> cites Stangs' <sup>91</sup> case of a boy five years old who sickened with ascites and enlarged glands in the abdomen. At autopsy the chief lesion was tuberculosis of abdominal lymphatic, but also tuberculosis of serous membranes and lungs. There was no tuberculosis in the family for two generations. The child had for years been in the habit of drinking milk warm from a cow, which, growing thin before the boy died, was killed, and found to be tuberculous, — how much or where is not stated.

Some of the above cases are quite conclusive, though not absolutely beyond the possibility of error. The other cases, though probable, are not conclusive, as the following case of Toulmin shows:

A child, breast-fed, of healthy family, in healthy house, did well till at the ninth week it moved to rooms previously occupied by a phthisical woman. In one week the child began to sicken, and died when four months old. The autopsy showed enlarged and cheesy glands in the anterior mediastinum; one small tubercle of the anterior wall of the right ventricle; lungs much affected, with cavity the size of a marble; bronchial glands cheesy and soft; spleen enlarged; tubercles in spleen, liver, kidneys; ulcers of jejunum, ileum, Peyer's patches, cecum and colon; mesenteric and retro-peritoneal glands enlarged and cheesy.<sup>41</sup>

On the other hand, Bollinger<sup>90</sup> has collected the cases of a number of families which habitually used milk from tuberculous cows without catching tuberculosis. Out of 22 families only one man was found who could possibly be called tuberculous, and this man used no milk, only cream in his coffee.

Typhoid patients afford a fair test of the infectiousness of milk. Here we have a large number of people with erosions and ulcers of the intestine; yet, in spite of their extensive milk diet, no one has discovered that tuberculosis is a sequel.

## HEMORRHAGES IN THE NEW-BORN.\*

BY CHARLES W. TOWNSEND, M.D.

THE occurrence of hæmorrhage in the new-born, from the gastro-intestinal tract and from other parts of the economy, has been frequently noted in Medical Journals, and various causes for it have been ascribed. Most of the text-books on children's diseases, however, including the new cyclopædia of Keating, say little or nothing about this disease except as it occurs in the form of umbilical hæmorrhage.

At the Boston Lying-in Hospital, out of 5,225 deliveries up to May 1, 1891, some 30 cases of hæmorrhage among the infants are recorded; while in the out-patient department, out of 2,000 deliveries, two cases are recorded; making 32 cases in all out of 7,225 cases, or less than one half of one per cent. The proportion of cases in the hospital is nearly six times that in the out-patient department, however, the percentages being .57 in the former case and .10 in the latter.

In the following paper I have endeavored to analyze these cases, and, in a brief manner, the literature of the subject, in order to arrive, if possible, at some conclusions as to the nature of the disease, its etiology, prognosis and treatment.

The *Clinical history* of a typical case is somewhat as follows: A baby, often well developed and apparently healthy, is noticed to vomit a little blood or bloody mucus on the second or third day of its life. The stools, which by this time should begin to assume the normal yellow color, still continue dark; but this brown color is found, on examination with the microscope, to be due to altered blood corpuscles. Oftentimes, however, this special examination is not necessary, for the napkins about the discharge are tinged red, or the blood is even voided in unmistakable quantities. The navel, about the insertion of the cord, or on the exposed surface, if the cord has already dropped off, is apt to bleed at the same time, and blood will ooze continually from any slight crack or abrasion of the skin. Epistaxis and bleeding from the mouth may also occur, and ecchymoses of greater or less extent may appear under the skin. Jaundice is frequently seen at first, to be succeeded by great pallor, as a result of loss of blood. The temperature may be elevated even to 106° F. Death or recovery occurs generally within three or four days.

In the 32 cases analyzed, 19 were males, 13 females, a proportion of the sexes which is significant when the relation of this disease to true hæmophilia is considered. Twenty-five cases died, seven recovered, a mortality of 78 per cent. The day of death in one-half of the fatal cases was from the third to the fifth day, one dying on the first day, and three as late as the fourteenth day.

Hæmorrhage was first noticed in two on the first day, in seven on the second day, in eleven on the third day, and in six on the fourth day. In the six other cases the hæmorrhage occurred between the sixth and the ninth day, with one exception, which began to bleed on the fourteenth day. The duration of the disease, from the time it was discovered, in nine of the fatal cases was but a portion of one day; in four, the disease lasted one day; in three, three days; and in three more, five days. Of those who recovered, the disease

lasted, in three cases, respectively two, six and eight days. In two cases it lasted three days, and in two more five days.

The sources of the hæmorrhage are given in the following table:

	Cases.
Intestine . . . . .	12
Stomach . . . . .	12
Mouth . . . . .	12
Nose . . . . .	8
Navel . . . . .	11
Ecchymoses of skin . . . . .	14
Crack of skin . . . . .	1
All of above sources . . . . .	3
Navel alone . . . . .	2
Gastro-intestinal tract alone . . . . .	15
Stomach, mouth and nose alone . . . . .	7
Intestines alone . . . . .	3
Ecchymoses alone . . . . .	2

Slight, uncomplicated hæmorrhage from the uterus or vagina, pseudo-menstruation, is not very uncommon in the first few days of life, and is not included in this list.

Although umbilical hæmorrhage, which is the best-known form of bleeding in the new-born, occurred in nearly half of the cases, it is interesting to note that in all but two of these cases there were hæmorrhages elsewhere, a fact which points to the general hæmorrhagic nature of the disease. This fact was brought out by Dr. Francis Minot, in 1852, in the monograph which first called the attention of the profession to this disease.

In one case a cephalhematoma occurred; in another persistent hæmorrhage took place from scratches on the face and foot. In six of the cases the temperature is recorded; in all but one of which it was elevated, reaching in one case 106.6°. In the case where there was no fever, the temperature was taken only once, four hours before death, and found to be subnormal. Jaundice was noted in five cases, cyanosis in four; and in all where much blood was lost the infant became blanched. In four, convulsions appeared before death.

Post-mortem examinations were made in six cases. In one case the liver showed an increase of connective tissue, and the diagnosis of cirrhosis was made. In another case a hæmorrhage was found between the brain and dura mater. In the other cases the results of the examination were negative. Two cases were believed to be syphilitic.

The mothers' labor was normal in all but four cases, three being delivered by forceps low down, one by version. Two of the mothers had mild septicæmia, all the others making normal recoveries.

In 609 cases collected from the writers, given in the bibliography appended to this article, including my own cases, and excluding duplicates, there were 482 deaths and 127 recoveries, or a mortality of 79 per cent.; 210 were male, 150 female, and in 249 the sex is not recorded. This would make a percentage of 58 male and 42 female.<sup>2</sup> I find records of 81 autopsies in this list. In the majority of cases nothing abnormal was found except extreme anæmia (which was the result of the bleeding), and in many cases internal hæmorrhages. Injection of the mucous membrane of the intestines, particularly of the colon, was frequently noted, although the observers are particular to state that no gross lesion of the mucous membrane was to be detected. In a very small

\* Read before the Boston Society for Medical Observation, June 1, 1891.

<sup>2</sup> For a number of these references I am indebted to Dr. Minot.

number of cases the following diseased conditions have been found: syphilis, enlarged spleen, enlarged liver, inflammation of the umbilical and portal vein, acute fatty degeneration.

The *prognosis* in this affection is poor, the average mortality, as noted in my cases, being 78 per cent.; but on examining the cases more closely, it is seen that the prognosis in cases of hæmorrhage involving the gastro-intestinal tract alone, — sometimes called *malena neonatorum*, — is slightly better, but 71 per cent. of these cases proving fatal. I have reason to think, however, that the prognosis is even better than these figures show, for the less serious cases of bleeding from the digestive tract may have not been recorded or not recognized. This latter error may arise in cases of discharge of blood high up in the intestine in moderate quantity. The blood then becomes changed to a dark, tarry color, so that the stools resemble the ordinary meconium stools. As before remarked, however, the blood can be detected by a microscopical examination, and in nearly all cases by the pink staining of the napkin on the border of the defecation.

There is a source of error which might lead one to diagnose hæmorrhage from the stomach when this is not the case. I refer to the fact that blood may be sucked from the nipples of the mother, in some cases from a crack or abrasion that can scarcely be detected. The presence of the abnormal substance in the infant's stomach excites vomiting, and the blood is ejected to the great consternation of the family, until the source of the hæmorrhage is discovered. It is said that maternal blood may be swallowed during delivery and afterwards vomited in the same way.

Where ecchymoses appear on the skin, in addition to the hæmorrhages elsewhere, the prognosis is worse. Out of eleven such cases only two recovered, although a fatal termination in these cases seemed imminent.

In making our prognosis it is to be remembered, therefore, that the prospect is not absolutely a bad one, even in the worst cases where ecchymoses appear on the skin, and the prognosis is the best in cases involving the gastro-intestinal tract alone.

Another point, it seems to me, is of value in making the prognosis, and that is, that the disease is, in nearly all cases, but of a temporary or self-limited character, confined almost entirely to the first ten days of life; and the longer the baby lives, the better are its chances for recovery. In other words, in the majority of cases, it is not the fact, as is often supposed, that these infants are affected with true hæmophilia, and are therefore doomed, even if they recover from the present attack, to subsequent and possibly fatal hæmorrhages. The reasons for this statement will appear later on.

The *etiology* of this disease is a subject about which much theorizing has been done, and I shall content myself with a brief outline of the causes assumed by various writers.

In the first place, prolonged labor, early ligation of the cord, plethora, debility, retention of meconium, difficulty in the establishment of the pulmonary circulation from obstruction to the breathing at birth, may, one or all, owing partly to the normal injection of the blood-vessels of the intestine of the new-born, act as exciting causes in this disease; but one or several of these conditions are so frequently met with, without such dire results to the child, that they can, it seems to me, be properly excluded from the true causes. More-

over, cases of hæmorrhage occur without these exciting causes. Septicæmia, in severe form (the source of infection being generally the umbilicus), and syphilis are, in a small number of cases, the causes of the bleeding. Rupture of large blood-vessels, as a source, has been disproved by all autopsies.

True inherited hæmophilia is in but rare instances the cause; and the arguments in favor of this statement are briefly: (1) The fact that infants who bleed during the first few days of life, and recover, are not apt to be bleeders in after life. (2) Hæmorrhages in the new-born, as shown by my cases and by the larger ones given above, are only slightly more common among males than females (58 to 42), while among true bleeders the preponderance of females is extremely marked, being stated at 13 to 1, or 92.8 to 7.2.

(3) In bleeder families the tendency is rarely shown before the end of the first year. Thus, Grandidier states that only 12 infants in 185 bleeder families with 576 individual bleeders were affected with hæmorrhage on the fall of the umbilical cord. Moreover, it is extremely rare among the large number of cases reported by various authors for a family history of hæmorrhagic tendency to be obtained, although this is a point that would certainly be known if it existed, owing, as Partridge well says, to its dramatic nature.

Confirmatory of the first of the above statements is the fact that, in several instances, infants who had recovered from an attack of hæmorrhage during the first week of life, have been circumcised a few days later without unusual hæmorrhage taking place. Two such cases are recorded by Ritter and one by Rotch. In two cases on my list bleeding occurred from the base of the cord as well as from various mucous surfaces, but the patients recovering, the cords dropped off, in one case on the eighth day, in the other on the eleventh day, without further hæmorrhage at this time. In the former of these cases the cord fell off in two days, in the latter four days, after hæmorrhage had ceased.

Deficiency in the nutrition or elasticity of the capillary walls, acute fatty degeneration of the new-born, feeble coagulability of the blood, and jaundice, are explanations sometimes given for this disease.

The self-limited character of the affection, the elevated temperature in some cases, and the greater prevalence in hospitals, are arguments of force in favor of an infectious nature; and Klebs and Eppinger have found in these cases a micro-organism (*monas hæmorrhagica*). In support of this view, Ritter says that while there were previously many cases yearly at the Prague Foundling Hospital, there was only one following the use of new and larger wards. The disease, as ordinarily seen, can, however, have no connection with puerperal septicæmia, for that disease is now practically eradicated from the Boston Lying-in Hospital; but it occurs independently of it, just as thrush caused by *oidium lactans* may get a foothold and flourish in a hospital free from septicæmia, although thrush is not common in private practice. In fact, more than two-thirds of the cases occurred in the Lying-in Hospital after the adoption of the antiseptic system.

In the *treatment* of this disease or symptom of disease many measures have been adopted, and also none at all, the latter from a feeling of helplessness in regard to it, and also, as we have shown, the erroneous belief that in all cases, even if the infant survived, it would always be subject to hæmorrhages. Bearing

in mind the brief course and self-limited character of the disease in the majority of cases, we should make every effort to control hæmorrhage and to sustain the vital powers. External bleeding from scratches or from the umbilical wound can best be checked by properly applied pressure; and although compresses for this purpose often fail, digital pressure, if intelligently directed and persisted in, is almost always successful. Instances are on record of devoted mothers and nurses, who, by holding their fingers pressed for hours to the umbilicus, have saved the infant's life. Styptics are generally unsatisfactory; and deep suturing of the umbilical wound, although in some cases successful, in others only adds a fresh source for hæmorrhage from the stitch-holes.

The value of astringents, of ergot or of mineral acids, for internal hæmorrhage, are of somewhat doubtful value. Alcohol, by increasing the power of the heart, would theoretically increase the bleeding; but, if we accept the belief in the infectious nature of the disease, it would seem in many instances to be indicated. Warmth to the extremities, perfect quietude and freedom from motion, and most careful and persistent feeding from spoon or dropper with milk drawn from the breast of the mother or wet-nurse, might tide over many otherwise fatal cases through the brief period of this disease. Antiseptic treatment of the cord would be indicated for prophylaxis.

## SUMMARY.

- (1) Hæmorrhage in the new-born is in nearly all cases an acute transitory affection, beginning within the first week or ten days of life and lasting from one to six days.
- (2) The etiology of this form is perhaps best explained by the infectious theory.
- (3) In very exceptional cases the disease is due to true hæmophilia as it is seen in older children and in adults. In a small number of cases it is one of the symptoms of syphilis or of septicæmia.
- (4) The mortality from all forms is about 75 per cent.
- (5) Treatment should be guided by the knowledge of the transitory and perhaps infectious character of the affection as it is seen in the majority of cases.

## Reports of Societies.

## BOSTON SOCIETY FOR MEDICAL OBSERVATION.

JOHN C. MUNRO, M.D., SECRETARY.

REGULAR meeting of the Society Monday, June 1, 1891, Dr. J. H. McCollom in the chair.

Dr. J. A. JEFFRIES read a paper on

THE SOURCES OF INFECTION WITH TUBERCULOSIS.<sup>1</sup>

DR. JACKSON: I have nothing to add to Dr. Jeffries' paper. I think it is a most exhaustive study of all that has been written up to the present time.

It has always seemed to me difficult to understand how any observers should feel that any considerable number of cases of tuberculosis was due to intestinal infection. Certainly, clinically, the vast number of cases have the most advanced lesions in the lungs or in the upper respiratory tract; and autopsies prove

<sup>1</sup> See page 211 of the Journal.

the same thing. I would like to ask Dr. Jeffries if it is Baumgarten who thinks that tuberculosis is chiefly caused by infection from the gastro-intestinal tract.

Dr. JEFFRIES: Yes.

Dr. JACKSON: He is the most prominent writer who feels that tuberculosis is due in a large proportion of cases to ingestion and not to inhalation. It seems very difficult to understand how such a man should express himself in that way.

When we come to consider the ingestion of tubercle bacilli, I think we can find, as in kissing, a much readier (or at least more probable) source for the ingestion of tubercle bacilli than in any other way. You know the enormous numbers found in sputa and in saliva. There is certainly the readiest mode of infection. That, I think, should be very largely considered in children who develop acute tuberculosis when they have been nursed by mothers in advanced phthisis.

Dr. TOWNSEND: Did I understand that where tuberculosis occurred owing to the ingestion of tuberculous food there was always some local intestinal, or at least mesenteric lymphatic, infection?

Dr. JEFFRIES: No. The evidence is that probably there are a good many cases where there is no disease at point of entrance, but curiously enough there are men who claim that tuberculosis chiefly springs from the intestine, who also hold that there is a pathological product at the seat of entrance. The position they hold is difficult to explain. Where any material amount of bacilli are introduced in the food we always do find the intestines affected.

Dr. McCOLLOM: One or two practical points are the disinfecting of the sputa, if the indirect doctrine is true, and I do not think that is carried on as thoroughly as it should be. I think very few physicians in private practice ever think of causing the sputa to be disinfected. It is a very important factor. The sputa becomes dried, and the bacilli will float in the air. In the German hospitals the consumptives carry a spittoon filled with a solution of carbolic acid, which is kept thoroughly air-tight. The man expectorates into it and closes it, so that there is no expectoration on the walls or floors of the hospitals. In this country people are constantly spitting anywhere. Go into large public gatherings, and the floor will be covered with expectoration, and a great many of these people may be suffering from phthisis in a latent or comparatively mild form, and this may be sufficient to give rise to the disease in a great many people.

Another practical point is the importance of having the streets properly watered, because there is no doubt that the dust does contain the germs of disease, and blowing about in such large quantities as is frequent, it seems to me it must very frequently cause the disease.

Dr. JEFFRIES: As regards the streets, it is a curious fact that the street-sweepers of Europe seem to be rather exempt than otherwise from tuberculosis.

Dr. McCOLLOM: It is possible they may become habituated to it.

Dr. JEFFRIES: They hold their occupation during life, and seem to be rather better off than other people as regards tuberculosis.

Dr. C. W. TOWNSEND read a paper on

#### HEMORRHAGES IN THE NEW-BORN.<sup>2</sup>

Dr. JACKSON: I should like to ask whether he finds in these cases small petechiæ as well as ecchymosis?

Dr. TOWNSEND: I used the word ecchymosis meaning any hæmorrhage under the skin. Many of them were very minute, very small petechiæ, in fact the majority.

Dr. JACKSON: Similar to the lesions in purpura?

Dr. TOWNSEND: Yes.

Dr. NICHOLS: I can recall in my own experience but a single fatal case of hæmorrhage in the new-born infant, and I remember to have recognized in this instance that the death was perhaps attributable to my failure to appreciate the gravity of the situation. The child was large, born of a healthy mother, weighed about eleven pounds, and, though forceps were applied, no unusual amount of force was necessary for extraction. There was no bleeding from the umbilicus, but as I was about to go, my attention was called to a slight oozing of blood over one zygoma, and upon examination I found that the forceps had made a superficial bruise at this point. The flowing, though slight, was persistent, and when an attempt was made to control it by means of stitches, the only result was a fresh source of hæmorrhage from the stitch-holes, which seemed, however, after a while to be controlled by firm compression, and the infant was, therefore, left with a pad bound to the cheek. Owing to a lack of intelligence on the part of the nurse, which should have been noticed and guarded against by myself, the bandage was not properly watched during the night, and there occurred a fresh flow of blood which proved fatal before a physician could be obtained.

Dr. JACKSON: As far as I know the only evidence offered in the direction of the infectious nature of the disease is in the direction of the clinician, that several cases generally occur together, that cases occur in hospitals more than in private practice and run this sharp acute course.

I do not know anything about the existence of this organism that Dr. Townsend speaks of. I know that in an allied disease, purpura, the existence of an organism has been claimed very different from the one Dr. Townsend speaks of. It never has been proven, as far as I know, though one or two observers have claimed they have produced the disease in animals by inoculation of the blood. That, I think, would not hold as absolutely true, because the inoculation of healthy blood has produced ecchymosis in animals; that is, I suppose, merely mechanical.

Dr. JEFFRIES: As this hæmorrhage begins almost at once after birth, it seems to me, if we are to have infection, it must have been before birth; and in those cases it is hard to say how it got into the fœtus without showing itself in the mother.

Dr. McCOLLOM: The fact that it occurs more frequently in hospitals than outside, I very much doubt, if it is not due to the fact that the cases are much more likely to be reported in hospitals than in private practice.

Dr. TOWNSEND: I have the report of the out-patient department; and the proportion is six times greater in the hospital than outside. The cases are carefully reported by the externes.

Dr. JEFFRIES: Is it not probable that the cases that come on late are infectious, while those that come on early are congenital?

Dr. MUNRO: Is there any evidence that these occur only in children badly nourished through the placental circulation?

Dr. TOWNSEND: Not at all. That is a cause some-

<sup>2</sup> See page 218 of the Journal.

times given; and another cause is that the child is plethoric. There is no rule either way about it.

DR. C. M. GREEN: I remember one case, the only case I ever saw, a child of healthy parents, the mother especially so. I delivered the child, I think, about ten years ago. It was after I had ceased my visits, and I only heard of it being called in for something else. I was told the child was lying in the cradle, and seemed perfectly well. It may have been two or three weeks old. They said they were attracted by some little noise, and went to the child and found it bleeding from the mouth. It bled to death. It was a very large child, and I delivered it with forceps. The child had done perfectly well, but died then and there. The mother has since had healthy children, but I never knew what the explanation of that case was. I do not think the child was seen by any physician.

This paper was not intended to cover, I suppose, hæmorrhages of the kind that Dr. Nichols referred to. Certainly the abrasion in his case was not sufficient to cause bleeding like that, without some bleeding diathesis I should think. But infants do have traumatic hæmorrhages which would not come under this category at all; small cerebral effusions, and effusions perhaps from undue violence in operating. Dr. Townsend will recall one case of breech extraction, where I think he made the autopsy and found a cerebral effusion, which, as I remember, he could not account for at the time, being a breech case. I have thought of it, and wondered what could have caused the death of the child. The head was exposed to no violence at all. The child died on the fifth or sixth day.

DR. TOWNSEND: Besides the cerebral hæmorrhage there were two large cephalæmatomata which appeared. There was no difficulty in the extraction of the head, and no pressure applied to the head.

DR. GREEN: That was the peculiarity, that the child should have had cephalæmatomata, although there was no compression of the head except going through the normal pelvis; and it also had cerebral effusion. Possibly this might have been a case of hæmophilia. I have never been able to explain in my own mind why that case should have occurred, unless it were from that diathesis. Bleedings from the navel are occasionally reported and seen. I remember a case of Dr. Richardson's several years ago, where the child bled from the navel. It recovered with medical, and not surgical, treatment. There was this constant oozing from the navel, and the child was in such a dangerous state that it was watched constantly. Deep stitches were passed, and everything done in the surgical way to prevent the bleeding. I think compression was used a good deal. Possibly that helped it; but the child was put on doses of the tincture of the chloride of iron, and after hanging in the balance some days, it finally got well. It was several weeks, I think, before it was considered out of danger. I believe it had ergot also.

I recall one case where the child died from hæmorrhage from under the liver. It was a question as to what caused the bleeding; it may have been from violence, possibly from a fall, although no history could be obtained. This was a forceps case (not my own), and there was also a cerebral effusion.

It is an extremely interesting subject and I wish we knew more about it; but I think we shall do well to remember that these cases are susceptible of treat-

ment, if they live long enough to be treated, by putting them on iron. Of course, where they run so short a course there is no time for medical treatment to have any effect.

The ordinary bleeding from the navel due to carelessness, does not come into the discussion. That is a thing we are occasionally reminded of where children have been left with one ligature which seemed sufficient, and afterwards bled seriously or fatally. I learned my lesson several years ago as regards care, from a case that I delivered with forceps. I was very busily engaged in sewing the perineum, and had forgotten the instruction I had received and always give, not to forget the navel. The nurse, fortunately for me, happened to think of it. She found the baby bleeding considerably, and yet I tied the cord as carefully as I knew how. I came to the conclusion that tie the cord as carefully as you may there is always the risk, and it should be looked at several times, as often as every fifteen minutes, up to the time the nurse takes it to wash it, and then the second ligature should be put on.

DR. NICHOLS: In reading a number of cases of fatal hæmorrhages in the new-born I have been impressed with the comparatively small amount of blood that has been lost, quite insufficient to account for the shock or cause of death, and I should like to ask the reader whether his experience would or would not confirm this impression, namely the danger of the comparatively small amount of hæmorrhage.

DR. TOWNSEND: I think in some of these cases there may have been an error. The amount of blood from the navel may have been small, but there may have been hæmorrhage from the stomach or bowels which was still retained inside of the body, and the child practically bled to death without very much blood escaping. In the cases reported and in the cases at the hospital the babies are almost always very much blanched at death. Of course, however, the amount of hæmorrhage sufficient to kill an infant is very small compared with that in an adult.

DR. MUNRO: Apropos of what Dr. Green said I should like to ask if there are any cases reported of hæmorrhages in children whose mothers had been given iron for some months before delivery, as is the custom with a good many obstetricians, and whether that would not be a preventive. Iron is notably a hæmstatic under any condition.

DR. TOWNSEND: I do not know. It seems to me these cases running such a definite course with elevated temperature ending with death or recovery in three or four days, form almost a definite class by themselves. Of course, in some of the cases, the hæmorrhage is simply a symptom of some other disease, as syphilis or septicæmia.

DR. JEFFRIES: Was the spleen enlarged?

DR. TOWNSEND: In the majority of the cases the record of the autopsy is absolutely negative. In some the spleen and liver were enlarged.

THE CLIMATOLOGIST, a new monthly journal devoted to the relation of climate, mineral springs, diet, preventive medicine, race, occupation, life insurance and sanitary science to disease, appears for the first time this month. It is edited by Drs. John M. Keating, Frederick A. Packard and Charles F. Gardiner, and thirty-one associate editors.

THE NEW YORK ACADEMY OF MEDICINE.  
SECTION ON ORTHOPEDIC SURGERY.

STATED Meeting, April 17, 1891, SAMUEL KETCH, M.D., Chairman.

DR. ROYAL WHITMAN presented a series of cases illustrating

## THE TREATMENT OF KNEE- AND ANKLE-JOINT DISEASE IN YOUNG INFANTS,

by an adaptation of Thomas's splint. He claimed that by the routine use of extension, not merely for its effect on the contracted knee, and as a factor in the production of rest, but for the purpose of retaining the brace in position, instead of using the ordinary shoulder strap, the constant shifting of the ring, which occurs in infants, is avoided, and hence, the irritation of the skin and motion of the diseased joint were reduced to a minimum. He advised the use of a brace in cases of ankle-joint disease, even when the infant has not begun to walk, on the principle that children long before they walk are making constant attempts to stand, and in creeping or otherwise, expose the joint to injury.

The brace is made of light material, with two leather straps attached to the foot-bar. The extension plasters are applied to the leg, usually below the knee, and the leg is firmly bandaged from the toes to the groin, and the brace applied with sufficient extension to hold the ring firmly in its place. The leg and brace are then firmly bandaged to one another, from the foot to the ring. Such an arrangement provides rest, compression and protection, the effect of which in painful, contracted and suppurating joints, is at once apparent. In ankle-joint disease, the foot being at a right angle to the leg, a well-fitting plaster bandage is first applied.

It seemed to the speaker that the treatment of joint disease in infancy should be carried out on the same principles as apply to older children, and that in cases of knee- and ankle-joint disease the conditions are most satisfactorily met by the Thomas brace. With ordinary care, its use was attended with no difficulty, and it was not unusual to see infants of from fifteen to eighteen months of age, walking about on the brace and high shoe, without discomfort.

DR. V. P. GIBNEY said that his clinical experience had taught him that it was almost impossible to hold the limb down with plaster-of-Paris in these small children; for, notwithstanding the performance of tenotomies, as soon as the plaster becomes soft, which it will do speedily, as a result of the dribbling of the urine and from other causes, the limb will begin to flex again. This adaptation of the Thomas splint he considered an admirable one.

DR. JOHN RIDLON said that this method of employing traction had been used by Thomas years ago, but more recently that surgeon had preferred to straighten the cases, with or without an anesthetic, and then put them up permanently in a straight position with absolute immobilization, and with as much traction as could be obtained by a full-length caliper splint. He thought that direct backward pressure, with a pad above and below the knee, and a strap behind the knee, was better than the method of bandaging adopted in one of the cases presented. For the ankle-joint cases he thought a metal splint was more satisfactory than the plaster-of-Paris. He had repeatedly tried plaster-of-Paris in these cases, and had found that it failed to keep the limb straight.

DR. JUDSON doubted whether, in larger children, the splint shown could be relied on to secure both fixation and protection.

DR. A. M. PHELPS disagreed entirely with Dr. Ridlon as to the superiority of a metal splint over the plaster-of-Paris. He has used the Thomas splint for the past four years as a protection to the joint, but he did not approve of producing extension by it, as this caused intra-articular pressure. His plan was to reduce the deformity under ether, and then apply plaster-of-Paris. He did not think the splint exhibited any better than plaster-of-Paris for small children before they began to walk.

DR. W. R. TOWNSEND said that it was because they had experienced so much trouble from excoriations in the use of plaster-of-Paris at the hospital, that Dr. Whitman had devised this arrangement.

DR. N. M. SHAFER saw no necessity for either this splint, or for plaster-of-Paris. There had been no trouble from the apparatus which he had employed in his practice, and he thought it gave even better protection than the Thomas splint. The deformity is usually made too important a factor in the treatment. A study of nature's methods would show that the deformity should be reduced by modifying, rather than by increasing the intra-articular pressure, and Dr. Whitman committed an error in attempting to reduce the deformity quickly, for, in the majority of cases, nature endeavored to warn us against this rapid reduction of the deformity, by establishing a condition of muscular resistance. The slow method of reducing the deformity, in his opinion, gave better ultimate results.

THE CHAIRMAN endorsed the views of the previous speaker. Some of these cases had been stated not to have had reflex spasm, but he could not understand how this could be the case, as in his experience, spasm had been invariably present. The apparatus acted upon the principle of the simple perineal crutch, and only emphasized the necessity for using this crutch in all these cases.

DR. WHITMAN, in closing, said that the only claim to originality which he made, was in the manner of holding the brace firmly against the groin. He was fully convinced that plaster-of-Paris was very undesirable for young infants, as the joint was often swollen to the size of the thigh, and the plaster speedily worked down and became loose. However beautiful might be the theory of increasing the intra-articular pressure by traction made with this splint, the fact still remained, that while the limb was being brought down, these children were comfortable, their general condition improved, and the joint diminished in size. The bandaging to which Dr. Ridlon alluded, was not for the purpose of straightening the leg, but to hold the brace firmly. He considered that the deformity *was* of much importance, and the sooner it was reduced, especially in knee disease, the better. If seen moderately early, one could be sure that recovery without deformity would occur, with the exception of some shortening.

DR. GIBNEY presented a case of

## ANTERIOR POLIOMYELITIS,

which had so affected the adductor group of muscles, as to cause marked deformity of the limb. When six years old, the patient was reported to have had a high fever, accompanied by inability to move the legs. This

condition rapidly improved, and then it was noticed that the child could use the limbs but little. He had first seen the case on November 16, 1887, at which time there was complete adduction of the limb, the hamstrings were considerably shortened, and there was some flexion at the hip. Shortly after, he began treatment by stretching the hamstrings, the case passed under the care of a distinguished general surgeon, who presented her to the Surgical Society as a case of congenital dislocation of the hip. She returned after a time, and the extension was resumed. On November 22, 1889, she was anesthetized, and by an open incision over the tensor vagina femoris and flexors of the thigh, he was able to divide freely the contracted tissues, until the limb could be brought into good position, when he applied plaster-of-Paris from the axilla to the toes. After two or three weeks, a brace was applied. On October 22d, another operation was necessary. On March 26, 1890, the limbs were parallel, and at present, it is difficult to produce any luxation of the hip-joint, the limbs are of equal length, and the child can walk fairly well without any apparatus. He thought the case showed the advantages of protecting the weakened muscles for a long time.

Dr. SHAFER said that he wished to emphasize the important part played by the tensor vagina femoris, this muscle and the sartorius often being the principal opponents to good locomotion. He had seen several cases in which the general surgeon had made a diagnosis of dislocation of the hip, owing to the extreme malposition of the thigh. Division of the tensor vagina femoris, and of the muscles attached to the anterior spine of the ilium, is the only method of treating these cases successfully, and to make the division thorough, he preferred the open method to the subcutaneous.

#### A CASE OF NECROMIMESIS.

Dr. W. R. TOWNSEND presented such a case. A girl, fourteen years of age, having a good family history, fell on the 27th of last January, twisting the foot, and producing a slight excoriation on the ankle. She was taken to a hospital, where the injury was treated by plaster of Paris for five weeks. On removing the plaster, the foot was found to be much distorted. She then came under the speaker's care, and an examination by Dr. B. Sachs indicated that the deformity was entirely due to psychical causes. There is now a slight equinus, and the extreme contraction of the tibialis produces varus. Only a slight force is required to bring the foot into the normal position, and the patient can retain it in this position, by the power of the will, for a few moments. There had been but little improvement so far in the case, which had been treated only by the application of blisters to the lower end of the spine, and by the administration of tonics.

In answer to a question from Dr. Ridlon, Dr. Townsend said that the genitals had not been examined.

Dr. RIDGON said that he asked this question, because in a recent case, a vulvitis had seemed to be the cause of the trouble.

Dr. SHAFER said that some time ago he had presented a somewhat similar deformity of the foot, but in his case there was a rhythmic action of the muscles of the thigh.

Dr. H. L. FAYLER thought the diagnosis was unquestionably correct. Some years ago he had had a very similar case, which began with a slight sprain, and which was completely cured in about one month.

Dr. R. H. SAYRE called attention to the remarkable resemblance which this purely muscular deformity bore to that seen in cases which are considered to be incurable except by the removal of considerable portions of bone. In this case the bony prominences are marked, and yet the bones are not luxated.

Dr. H. W. BERG spoke of the possible medico-legal interest that might attach to such cases.

Dr. CHARLES N. JONES, of Brooklyn, presented a boy, six years of age, who was admitted to the Children's Hospital on September 10, 1890. He had a rachitic history, and all the bones presented rachitic deformity. The teeth were deficient, and the femora presented anterior and lateral curvatures, with great depression of the internal condyles. Below the knee, in both legs, there was a marked anterior and inward angular deformity of both bones of the leg.

On October 21st, 1890, he performed supra-condyloid osteotomy of both femora. The wounds were dressed antiseptically, put up in plaster splints, and suspended by weights and pulleys, as recommended in an article published in the *Annals of Surgery*, April 1889. On November 15th, he performed cuneiform osteotomy on the tibiae and fibulae of both legs, for the correction of the principal deformity. The wounds were dressed according to the method recommended by Von Bergmann, namely: they were thoroughly packed with iodoform gauze, dressed antiseptically, and left until the following day, until all hemorrhage had ceased, when the bones were united with catgut sutures, the periosteum and the skin wounds sutured, and the limb enveloped in a mass of sublimate gauze. Plaster bandages and suspension were then applied as before. Recovery was uninterrupted. On January 9th, an additional section of the bones of both legs was made to correct a slight remaining deformity, and the same after-treatment was adopted. The patient presented a very tight and adherent prepuce, which was a constant source of irritation to him. At the first operation, he was circumcised. This apparently slight operation the speaker considered important, as he had found it necessary to perform it in the case of every deformity in a male child which had come under his observation.

#### THE PLACE OF FIXATION IN THE TRACTION TREATMENT OF HIP-DISEASE.

This was the title of a paper by Dr. ROBERT W. LOVETT of Boston, who illustrated his remarks by the exhibition of apparatus. He said that it was a question for those who believe in the traction treatment of hip-disease, to consider whether apparatus should have as its object, simply traction, or fixation of the joint as well. This question presents itself under two aspects: (a) As to the advisability of using in certain cases a splint which should give better fixation than the long traction splint; and (b) The indications for fixation in bed, and the class of cases in which it is necessary.

The long traction-splint was introduced under the impression that it was an appliance which should give motion without friction. Later, traction in itself came to be regarded as a means of fixation, and Dr. Judson was the upholder of the view that traction furnished fixation to the hip-joint. Some experiments by the writer tended to prove that the long traction-splint was not a fixation appliance, and one worn by a boy with normal hip-joints, allowed motion of 35° in walk-

ing and sitting. The practical question arises whether such a splint furnished enough fixation, or whether in certain cases more perfect fixation of the joint is not to be desired. Certain cases do badly under treatment by the long traction-splint, and these seem to be of two sorts; very severe cases, and cases where the patients are under imperfect control, and run and play continually, producing traumatism of the joint, which results in sensitiveness, irritability and malposition.

In the hope of preventing this condition in such cases, a splint was shown which was practically a combination of the Taylor and Thomas splints. The appliance fixes the thorax, the pelvis, and the leg, and comes below the foot, ending in a traction appliance, in this way fixing the hip-joints as perfectly as possible, and at the same time making traction upon the diseased limb. The writer would advocate the use of such a splint chiefly in hospital practice, in very severe cases, and in patients under imperfect parental control. Practical experience has shown the splint to be useful in this class of cases.

(b) With regard to the second division of the subject—fixation in bed—the experience of the Boston Children's Hospital has been that the immediate treatment of malposition or joint sensitiveness results in a very small proportion of abscesses among the cases treated. Of 182 cases admitted in the last three years, 107 were sent to the wards on account of deformity and sensitiveness, and only 52 for abscess. In these years, the percentage of cases admitted for deformity and sensitiveness has steadily increased, while the percentage admitted for abscesses has steadily diminished. In the last six years at the Children's Hospital, among 574 new cases of hip-disease coming in that time, only 107 abscesses have developed, giving a percentage of 18.7 per cent., which is very much less than any other series of cases reported. Of Dr. Gibney's cases, sixty per cent. had abscess; in the Clinical Society's cases, sixty-nine per cent.; and in the recent cases of Mr. Marsh, fifty per cent. It has seemed that the early admission of cases was to be regarded as the preventive treatment of abscess. It would seem, therefore, that the use of a splint affording more fixation than the ordinary traction-splint was needed in severe and sensitive cases, and that rest in bed was advisable when malposition occurs, not only in order to overcome the malposition, but in the hope of preventing abscess.

Dr. RIDGON approved of the author's observations upon the traction-splint, but the outline of the splint which he had exhibited was certainly improper. During the last few years he had not found occasion to employ more traction than was obtained by the tendency of the Thomas splint to work downward. If the splint were not supported by shoulder-straps, it gave sufficient traction for the successful treatment of fractures of the upper part of the thigh-bone. He questioned very much advisability of allowing the patient to walk around, who had sufficient muscular spasm to indicate the necessity for the application of a special traction apparatus.

Dr. SHAFFER thought that the author's experiments to determine the amount of motion occurring at the joint were fallacious, as they did not take into account the considerable arc of motion produced by the flexibility of the lumbar spine. He thought that his own experiments upon this point had not yet been contradicted. In these, he applied the apparatus to a healthy hip-

joint on a person whose opposite joint was ankylosed. A person with an ankylosed hip can walk, or even dance, owing to the flexibility of the neighboring parts.

Dr. JUDSON thought that the traction-splint secured fixation but not immobilization. He thought it was important to make this distinction. Immobilization is found in union after fracture and in ankylosis, while fixation is produced by reflex muscular action and by traction. It is almost impossible to immobilize a joint by any application of mechanical surgery. Fixation implies a degree of mobility which allows a reduction of the deformity. When applied in a painful case, it has a wonderful effect of relieving the patient's distress, which is partly main and partly a sleep-destroying apprehension of disturbance of the joint.

Dr. PHELPS said that as he believed it was a cardinal principle in the treatment of all joint-diseases, that the affected part should be immobilized, he could not understand what the author meant by "motion within certain limits"; he saw no reason for the joint being moved at all. During the period of pain, we all agreed that rest in bed was the proper thing, and yet, if this represented the best method of treatment, why employ a splint which would not carry out this idea? More than seventy-five per cent. recovered without deformity. Again, if extension were the proper thing, why not counteract the action of the abductors and adductors which cause the spasm, by making use of lateral traction? He did not think the statistics about abscess collected by the author carried much weight, because in Boston these cases were sent to institutions at an earlier stage of the disease than they were here.

THE CHAIRMAN referred to an article by Dr. Judson, in which it was shown quite conclusively that the effect of mechanical treatment, when applied sufficiently early, was to prevent abscess, and that it even prevented the opening of many abscesses which had already formed at the time the treatment was begun. Long before the Thomas splint or the lateral traction splint were known here, Drs. Sayre and Davis obtained cures without deformity, by means of the traction apparatus commonly employed, and he would not, therefore, accept the view that almost all the cases treated by this much abused traction-splint, pursued an unfavorable course, and ended in deformity.

Dr. BERG spoke in favor of the use of apparatus which did not require any elaborate fitting; for, as he said, "Some braces require so much fitting that they rarely fit."

Dr. H. L. TAYLOR said that he was glad to be able to approve nearly all the points made by the author in his excellent paper. The hip-joint required some form of fixation as well as extension when acutely inflamed. In most cases, the amount of fixation afforded by the long counter-extension splint, combined with short periods of rest in bed, when necessary, was sufficient. Dr. C. Fayette Taylor had never claimed that his long splint gave positive immobilization of the hip, but the speaker was surprised at the range of motion found under its use by Dr. Lovett, and would wait for further experiment before admitting that the question of the amount of motion allowed was settled. In very bad or unruly cases in dispensary practice, the apparatus shown by Dr. Lovett would no doubt prove useful. The speaker would emphasize the advantage of properly applied counter-extension in the progressive stage of hip-joint disease, in order to restore the hygiene of the joint and prevent deformity.

DR. LOVETT said that he had used one perineal pad instead of two, because his object had been to find the fixative power of traction, and not of any special splint; and he thought his experiments, as far as they had gone, were in the proper direction. With regard to the question of abscess, he should have added, that the 170 cases of abscess mentioned included those occurring in cases which had been admitted for a number of years past, at least since 1880.

### Recent Literature.

*Historical Sketch of the University of Maryland, School of Medicine (1807-1890).* With an Introductory Chapter, Notices of the Schools of Law, Arts and Sciences, and Theology, and the Department of Dentistry, and a Catalogue of Medical Alumni. By EUGENE FOUNTLEROY CONDELL, M.D. Baltimore, Md.: Isaac Friedenwald. 1891.

This volume is primarily interesting to the Alumni of the University and to those living in Maryland and Virginia, but there is a great deal in it to interest those living in other States and all engaged in medical education, those desirous of becoming practitioners of medicine, and those who may be subjects of treatment. The history is long and full of detail, and at the commencement we are told that the first indication of a tendency towards a community of action and interest in the profession, was an interesting discussion in the newspapers upon the subject of medical reform and the suppression of quackery, which began in 1785 and was carried on for several years.

In July, 1788, a medical writer suggested that a law be passed restricting the practice of medicine to those duly qualified, and at the close of this year a petition was in circulation for presentation to the general assembly, praying that body to introduce measures for the better regulation of medical practice in this community. To this call, it is significantly added, that empires are most particularly prevalent in Baltimore. What would have been the writer's astonishment and disgust, could he have foreseen that the same statement would be equally true one hundred years later!

The medical society of Baltimore was formed in 1789 and lectures delivered the following winter, but it was only in 1807 that a bill of considerable length, with twenty paragraphs, was passed by the Legislature, incorporating the college, and with this preamble, "That, whereas it appears to this General Assembly that many benefits would accrue, not only to the State of Maryland, but to many other parts of the United States, from the establishment of a seminary for the promotion of medical knowledge in the city of Baltimore," etc. A board of regents, composed of physicians, was thus created, which met very soon after and chose six professors who commenced their work immediately, and this school has continued with success, though encountering many obstacles, to this day. The Legislature at one time interfered, and modified in important particulars, the charter, creating a new board of trustees, but after some years there was a law-suit and the original charter was reaffirmed. A great part of the time the management of the school was almost entirely in the hands of medical men, and these contributed much to the success of the institution. At an early date, a hospital, under the control of the medical faculty, was established.

We have short biographies, with photographic likenesses, of the various professors, many of whom were natives of and trained in New England. Dr. W. R. Smith was a very successful professor and manager of the school for many years, and contributed very largely to its success. His father, Dr. Nathan Smith, was, in his day, a pioneer of medical education; by his efforts a medical school was established in connection with Dartmouth College, another in New Haven, and another in Maine in connection with Bowdoin College. His last years were spent in New Haven as a professor in the medical school of Yale University. By such a father and with such surroundings was trained the most distinguished and efficient teacher of the University of Maryland. Dr. Roby was professor of anatomy and surgery at Bowdoin College, and for nine years also occupied the chair of the Theory and Practice of Medicine, of *Materia Medica* and Pathological Anatomy at Dartmouth College. For eighteen years he was the Professor of Anatomy and Physiology in the University of Maryland, and during two years he also delivered the lectures on Theory and Practice; he was a very successful and popular teacher. Dr. John D. Wells, of Boston, was the professor of anatomy of Bowdoin College, and having great reputation as a teacher and lecturer, was appointed the professor of anatomy in the University of Maryland, but held the office only one year, death terminating his labors. Dr. Benjamin Lincoln, one of the most accomplished teachers of anatomy and physiology, of his time, succeeded Dr. Wells in the discharge of the duties of the anatomical chair. Dr. Elisha Bartlett, of Lowell, Mass., held the chair of Theory and Practice, resigning a position in the Transylvania University. Dr. Dunglison and Dr. Patterson were professors coming from Great Britain. Dr. Geddings from South Carolina. Many remarkable men have been connected with this school.

*Text-Book of Bacteriology.* By CARL FRAENKEL, M. D., Professor of Hygiene, University of Königsburg. Third edition. Translated and edited by J. H. LINSLEY, M. D., etc. 8vo, p. 376. New York: William Wood & Co., 1891.

Since its first publication, Fraenkel's Bacteriology has been the best concise text book to be found in the German language, and any one who has found the difficulty surrounding all teachers of the subject in this country will welcome the translation of the work here presented to us. It seems to us, however, that the change from the lecture form of the original, and the omission of the marginal notes, are a loss and not a gain. The book is likely to find its special usefulness in laboratory work, and for this purpose the omitted notes are of great value. The volume is well printed and bound.

H. C. E.

*Bacteriological Technology for Physicians.* With 72 Figures in the text. By DR. C. J. SALOMONSON. Authorized translation, from the second revised Danish Edition, by WILLIAM TRELEASE. Now York: William Wood & Co. 1890.

Salomonson's hand-book is a valuable addition to a laboratory library. Like most others of its kind, it contains hints that are not found elsewhere, but that are presented in a very simple and practical way. For so small a text-book it presents the subject exceedingly well; certain of its suggestions in regard to apparatus and methods will be very useful to the worker.

THE BOSTON

**Medical and Surgical Journal.**

THURSDAY, AUGUST 27, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.***SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.**All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.**Remittances should be made by money-order, draft or registered letter, payable to*DAMRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.**THE SEVENTH INTERNATIONAL CONGRESS  
OF HYGIENE AND DEMOGRAPHY.**

THE recent International Congress of Hygiene and Demography, held in London, August 10 to 17, was the seventh of the series. The first Congress owed its initiative to the Belgians, and was held in Brussels in 1876. At this meeting Dr. Lionville, who represented the French Government, proposed that a permanent organization should be effected and that meetings should be held at stated intervals. The next meeting was held in Paris in 1878, when the organization was perfected, and it was decided to meet every two years. Meetings have been held twice in Paris, in Turin, in Vienna and Berlin. Interest in the earlier meetings was mainly confined to the continent, England sending a comparatively small representation, until the previous meeting, which was in Paris at the time of the last French Exhibition.

England's real concern in and contributions to such subjects as general hygiene, preventive medicine and vital statistics have been so great that she certainly cannot afford to abstain from coöperation with her neighbors and with other nations in any movements for the discussion and furtherance of these objects. This seems to have been the purpose in view when it was decided to have the present Congress held in London, and anticipations of a remarkable meeting were both encouraged and indulged. A very elaborate and extensive programme was issued, the gracious patronage of the Queen was secured, the Prince of Wales accepted the Presidency and promised to open the Congress with an address, and the Lord Mayor to entertain the delegates at Guildhall; a large number of the leading corporations and sanitary authorities of Great Britain appointed delegates and contributed funds. The result was a tremendous foreign and native attendance.

The occasion, which should have been a great and memorable one in every way, was unfortunately, if we may trust the reports of the British journals at hand,

but barely saved from failure in some important respects. The very qualities which, of all others, one would have expected to find — executive capacity and prevision — seem to have been absent. The accounts of the foreign delegates arriving in London Saturday and Sunday preceding the Monday of opening, are almost pathetic for one who knows what the London Sunday may be for the stranger. No bureau of information was to be accessible before Monday. The entrance to Burlington House, the place of meeting, presented its iron gate closed, and the delegates seem to have found the only semblance to a friendly and hospitable welcome at a French café on Regent Street.

The arrangements on Monday seem to have been extremely inadequate. One journal says: "It is, however, impossible not to refer to what has already been the subject of much public comment, as well as very general dissatisfaction, in the relative break-down of the arrangements made by the Secretary-General. There was no reception or reading room worthy of the name, but only an ill arranged and embryonic office, which almost wholly occupied a quadrangle of bare deal counters; at this, on the opening day, a struggling mass of members, who became almost combative, attacked a small cohort of imperfectly-drilled clerks, nearly all of whom seemed incapable of speaking or understanding any foreign language, and each of whom seemed only to know a little about the particular cards with which he was entrusted, and to be quite unable to afford any general information or to refer to any inquiry office, or to any interpreters who could facilitate the general and natural hunger for information and invitation cards. . . . A curious want of perspective was apparent in the whole design by the executive of the arrangement of the proceedings, and a singular feebleness in carrying them out. Whether by inadvertence or from higher knowledge, of which the character has not been explained, the Congress was devoid of any features of *ensemble*. At the first meeting the proceedings were purely formal, nor were any occasions provided such as those which gave so much interest to the last international medical congresses of London and Berlin, at which the great scientific topics of the day should be handled on successive days in general meeting, by one or two eminent representative speakers from each of the countries represented. The result has been a curious incoherence and absence of unity in the proceedings, while the public are left unguided by any indication of the relative importance of the great subjects submitted for argument. The result has been a somewhat ill-digested jumble and a palpable want of perspective in the sanitary landscape presented to the public view."

The demand for cards to the Lord Mayor's reception far exceeded the supply, so that it was found necessary presently to draw for the remaining invitations, and in this lottery the foreigner was given no preference over the native. Notwithstanding the friendly countenance of and participation in the meeting by the Queen and Prince of Wales, the official repre-

representatives of the Local Government Board, the Bureau of Health, were conspicuous by their absence.

Though the Congress evidently failed in important respects to be all that it should have been, such a gathering of men representing such subjects from all civilized countries could not fail to make many contributions, both directly and indirectly, to the questions for the consideration of which it was called.

Sir Joseph Fayrer presided at the important Section of Preventive Medicine, and delivered the address, in the course of which some striking comparisons were made between the state of England in the Elizabethan and in the Victorian age. In regard to the influence exerted by the sanitary measures in the present century he states that :

"Under the improved system of sanitary administration which now obtains, and is gradually developing to a greater state of perfection, the sanitary administration of every district in the country is entrusted to the care of duly qualified health officers — a system from which excellent results have already accrued, and from which better still may be anticipated. The records of the past fifty years prove the influence exerted by sanitary measures on vital statistics. The first reliable tables from which the expectancy of life may be derived, show that in 1838 to 1854 it was for males 39.91 years, for females 41.85 years; by the tables of 1871 to 1880 it had increased to 41.35 for males, and 44.66 for females. It is shown also that the expectation of life increases every year up to the fourth year, and decreases after that age. For males up to nineteen years it is higher by the last tables, but after that age it is higher by the old table; for females it is greater by the new table up to forty-five, but after that age it is less. The improved sanitation saves more children's lives, but the conditions of gaining a living are harder than they were at the time of the first table, which accounts for the expectancy of life for adult men being less. Women remain more at home, where the better sanitation tells, and are not subject to quite the same conditions as men, so that their expectancy of life is greater than by the old tables up to the age of forty-five. A further proof of the effects of sanitary work is a decreased death-rate. Let us compare the death-rates of England during past times with the present; whether they be equally significant for other countries I cannot say, but these, at all events, sufficiently prove the point in question.

#### DEATH-RATE.

1600-70 . . . . .	80	per 1,000	1870-75 . . . . .	20.9	per 1,000
1601-50 . . . . .	42.1	"	1875-80 . . . . .	20.0	"
1716-35 . . . . .	35.5	"	1880-85 . . . . .	19.3	"
1816-35 . . . . .	24.9	"	1885-88 . . . . .	18.7	"
1860-70 . . . . .	22.1	"	1889 . . . . .	17.85	"

"In some parts of England, where the main object is the recovery or maintenance of health, the death-rate is down to 9 per 1000, while in others, where the main object is manufacture and money-making, it is as high as 30 per 1000."

The population of London to-day (5,600,000) is considerably greater than the entire population of the

whole of England (4,000,000) at the time of Queen Elizabeth, and is probably the greatest congregation of human beings the world has ever seen. London has more inhabitants to-day than have Paris, Berlin, Vienna and Rome combined. Sir John Coode, in the Presidential Address before the Section of Engineering in relation to Hygiene, touches somewhat upon the same ground as Sir Joseph, but from the engineer's point of view. He emphasizes the vastness of London by the statement that the streets and roads within the metropolis, if placed end to end in one continuous line, would measure about 2,500 miles, equal to the distance from London to Land's End, and thence across the Atlantic Ocean to the mouth of the Gulf of St. Lawrence in Canada on the west, or, going eastward, would extend across the entire continent of Europe, and beyond the Ural Mountains into Asia. The water supplied to its people is conveyed through pipes, the united length of which is about 4,760 miles. The total volume of water delivered for domestic purposes only in 1890 was 64,000,000,000 gallons (290,623,000 cubic metres). For raising this large quantity the companies employed no less than 184 steam-pumping engines, having an aggregate of 21,659 horse-power.

In regard to the drainage of London, Sir John says : "Whilst admitting that extensive drainage works have been executed, and that large expenditure has been incurred for improving the health of London, it cannot yet, by any means, be said that all has been done which might be done in this direction. Nor will it be possible to say as much as long as the sewage of the metropolis is allowed to flow into any part of the Thames without previous purification by the most perfect method as yet known — that is, by being filtered through land. The only alternative would seem to be the conveyance of the sewage to the sea-coast beyond the mouth of the estuary of the Thames. Nevertheless, and notwithstanding the room which exists for further improvement in the disposal of its sewage, the reduction which has been brought about in the death-rate of London in modern times is as noteworthy as it is satisfactory."

The real value of this Congress will probably become more evident as the great contributions to it become accessible, and the petty annoyances to which individuals were subjected will be forgotten. We expect next week to publish the account of our special correspondent.

#### A NATIONAL ASSOCIATION OF MILITARY SURGEONS OF THE NATIONAL GUARD.

A CALL has been issued to the surgeons and assistant-surgeons of the National Guard of the United States to meet in Chicago, on September 17th, 1891, at the Leland Hotel, for the purpose of organizing an Association of Military Surgeons of the National Guard of the United States, for the advancement of military and accidental surgery, and all things per-

taining to the health, usefulness and welfare of the civilian soldier.

During the last ten years there has been a marked and growing improvement in the personnel of the citizen soldiery; not alone the State, but the National Government has apparently recognized that upon this body of men would devolve in time of need the duty of national protection, as well as the minor duty of protection from mob violence, with which our large cities are constantly menaced.

The medical department of our National Guard is composed of earnest and zealous men, who are ambitious for the perfection of the Volunteer Militia of the various States, and it is proposed at this meeting to unite their mutual interests, and to bring before them such subjects as will be useful to the individual surgeons and their respective commands. Many of the surgeons are well-known men in civilian life, and bring to their military work new and fresh ideas, which have already in some instances been found to be of value. In Massachusetts the Ambulance Corps have brought into use a system of handling wounded which is well worthy of consideration.

There are many subjects in which a consensus of opinion of surgeons would be of value; as, for instance, the necessity and practicability of a physical examination of all Volunteer Militia or National Guards. At present, in some of the States, a physical examination is enforced, whereas in others no such examination is held, for apparently the reason that enlisting-officers are anxious to enlarge their commands.

The bill of dress which is given to the National Guards is one open to improvement. At present the men are arrayed in a uniform which is worn in our temperate zone in January and in July. As a matter of fact, the greater part of the work done by the National Guards is performed under a semi-tropical sun, and hence a bill of dress should be provided for this work. In the State of Ohio such provision is made, and the men in summer are put into a suitable uniform to withstand the heat of the sun.

The question of the proper supply of food to the militiamen is an active question. Further, the relation of the medical department to other departments, notably the quartermaster's, is a subject which might well be discussed.

The first treatment of wounded is a subject that is by no means threadbare, and a score of other practical questions will naturally arise for consideration.

In fact, the encampments of the State troops, as now conducted, are practically "schools of instruction;" and here an opportunity is afforded for the trial of ideas which may be found of value, and a meeting together of the medical gentlemen connected with the various State Militias cannot but be of great value. Various State Associations of National Guard Surgeons have been or are being formed; but our country is so large, its interests so varied, that on any mutual subject of interest the formation of a National Association ought to be productive of national good.

## MEDICAL NOTES.

**THE MEDICAL PRESS ASSOCIATION.**—It is proposed to have a meeting and conference of this association in St. Louis during the meeting in that city of the Mississippi Valley Medical Association, on October 14th, 15th and 16th.

**CHOLERA.**—In Mecca 33 cases of cholera were reported July 13. Owing to the presence of a number of pilgrims the disease spread rapidly, and, by July 19, 360 persons were affected. Cholera has also appeared in Abyssinia and in the vicinity of Mt. Atlas.

**THE POPULAR IMPRESSION OF LEPROSY.**—Dr. Cyrus Edson, chief inspector of contagious diseases of the New York City Board of Health, presents in the *North American Review* his reflections concerning the sensational articles that appear from time to time in the secular press on "that dread scourge, leprosy." He properly deprecates these articles as essentially wide of the truth and harmful to the uninformed populace.

**LEPROSY IN JAMAICA.**—Dr. Donovan, in his annual report to the Governor, on the Lepers' Home, Jamaica, estimates the leper population of the island at 450, or 1 leper to 1,380 of the population. Pending general legislation on the question of isolation, he recommends a prohibitive enactment against lepers keeping provision stores or being employed therein, or in the preparation of food; that no leper be allowed to engage in any of the following vocations, namely, baker, butcher, fisherman, tailor, school-teacher, etc.

**YELLOW FEVER.**—A serious outbreak of yellow fever has occurred this season in Vera Cruz. For some years that town had enjoyed comparative immunity from the disease. During the three years ending December 31, 1889, there were only nine deaths from yellow fever, or three a year. Last year the mortality rose to thirty-seven, a light record in comparison with the records of previous years.

**MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.**—This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues. Attendance as a delegate at an annual meeting of the Association is not necessary in order to obtain membership. On receipt of the above amount the Journal of the Association will be sent regularly.

**RECENT APPOINTMENTS ON DIFFERENT MEDICAL FACULTIES.**—The following appointments have been announced: Victor C. Vaughan, M.D., dean of the faculty of the medical department of the University of Michigan; Henry V. Wilson, M.D., recently in charge of the United States Fish Station at Wood's Holl, professor of biology in the University of Carolina; H. M.

Whelpley, M.D., professor of physiology and histology, director of the Histological Laboratory, and Secretary of the Missouri Medical College; Alexander C. Abbott, M.D., assistant director of the Hygienic Institute soon to be opened in Philadelphia; G. H. F. Nuttall, M.D., assistant in pathology and bacteriology in the Pathological Laboratory of the Johns Hopkins Hospital; Albert A. Ghriskey, M.D., assistant in bacteriology in the Hygienic Institute of the University of Pennsylvania; Henri A. Lafleur, M.D., assistant to the chair of practical and clinical medicine in McGill University, Montreal; Fred. J. Brockway, M.D., one of the demonstrators of anatomy in the College of Physicians and Surgeons, New York.

**EXPERIMENTS IN GUNSHOT WOUNDS.**—The army surgeons who have been attending the course of operations under the direction of Professor Kocher, of Berne, says the *Lancet*, have just been studying the destructive powers of the new Swiss rifle. In their presence have been practised several series of rifle shots, at ranges of from sixty to six hundred metres, with bullets proportionately varying in velocity. Among the objects fired at were materials of various kinds, including osseous structures and pieces of wood filled with liquid, in order to take note, by way of analogy, of the effects of the bullet on the living subject. These experiments have amply confirmed what has long been practically admitted, that at high velocities the bullet discharged from small bore firearms produces effects analogous to those of an explosive projectile.

#### BOSTON AND NEW ENGLAND.

**BOSTON CITY HOSPITAL.**—The Trustees of the Boston City Hospital have investigated the charges which were lately brought against the hospital management, the most serious of which related to overworking the nurses and attendants. These charges originated with a former hospital attendant, who we learn has been discharged. The report of the trustees exonerates the superintendent, and states that there are few hospitals in the country in which the staff of nurses is larger in proportion to the number of patients, or where the attendants are better remunerated.

**MEDICAL PRACTICE IN CONNECTICUT.**—The *Monthly Bulletin of the Connecticut Board of Health* contains the following reply, sent to a doctor inquiring of a State official if he would be allowed to practise in Connecticut by registering his name and the college from which he graduated: "SIR: Anybody can practise medicine in Connecticut. You do not need to register; you do not need a medical diploma; you do not need to know the difference between opium and peppermint; you do not, indeed, need to know anything. You can simply come and live here, and begin to practise. The laws of Connecticut will sustain you in collecting your fees for professional services, if you render any which you choose to call such. But if you undertake to carry me or my trunk to the depot for pay, you must get a license. If you peddle matches

or peanuts, you must get a license. If you collect the swill from your neighbors, to feed your pigs, you must get a license. If you want to empty your cesspool, you must get a license. But you can practise medicine in Connecticut *without a license*."

#### NEW YORK.

**THE DEATH-RATE.**—The number of deaths reported in the city during the week ending August 15th showed a considerable increase in mortality, due to the hot weather that prevailed. There were 1,005, representing an annual death-rate of 31.08 per thousand of the estimated population, as against 23.61 for the previous week. Much of the increase is naturally to be found in the infant mortality, which rose from 380 to 492; and out of 234 deaths from diarrhoeal diseases, 211 were in children under five years of age. About 100 deaths were due to exhaustion and sunstroke, and there was one case of fatal sunstroke in which death was at first supposed to be due to suicide, as a letter was found on the man's person indicating that he intended to commit suicide. At the autopsy, however, it was ascertained that the effect of the intense heat had anticipated his intention.

**TWO CASES OF TRICHINOSIS.**—During the past week two cases of trichinosis have been reported. The patients were a mother and son living in a crowded down-town tenement-house, and they contracted the disease by eating cheap ham. At last accounts both were improving.

**LEPROSY.**—Two Chinese lepers have been taken by the health authorities to North Brothers Island, where they will remain for the present in a finely equipped hospital tent. It is probable that they will eventually go back to China. In his report on these cases Dr. Cyrus Edison, Chief of the Bureau of Contagious Diseases, says: "The action now necessary for the Board of Health to take in the premises turns upon the contagiousness of leprosy. That the disease is contagious under certain circumstances numerous competent medical observers assert. Among these is the discoverer of the bacillus lepræ, Dr. R. Armeren Hansen. . . . The conditions favorable to the spread of leprosy are those existing in the so-called Chinese quarter in this city. Here we have a population consisting of people who are admitted by all authorities to be susceptible to the disease, among whom it is prevalent, by whom many claim it has been introduced into countries previously free from leprosy, as, for example, the Sandwich Islands and Australia." Dr. Benedict, an inspector of the Board of Health who was, at the request of the Newark Board of Health, sent to that city to investigate an alleged case of leprosy, has reported that the case is a well-developed one and that the patient is a Chinaman.

**DIPHTHERIA.**—Two of the medical staff of the Board of Health, Drs. Talley and Steele, have contracted diphtheria during the past week while engaged in the performance of their duties in the tenement-house region.

## Miscellany.

## A LETTER FROM DR. OLIVER WENDELL HOLMES.

The editor of the *Australasian Medical Gazette*, having seen a notice of a paper by Dr. Oliver Wendell Holmes, on the "Physiology of Quacks," forwarded to him in February last copies of the reports of and evidence taken by the Select Committee of the Legislative Council on the practice of medicine and surgery in New South Wales. He did this on the presumption that this celebrated author, having written on the subject, would feel interested in the life history of typical specimens of the same genus, as told by themselves. The subjoined letter was received in reply and alludes to his continued interest in matters relating to the medical world.

Boston, April 25, 1891.

My Dear Sir ;—I thank you most cordially for the very important and interesting papers relating to quackery as it appears in your great colony.

Although it is a very long time since I have practised medicine, I retain my interest in all matters relating to the profession, and am glad to add these valuable documents to my library, for the present, but to go eventually with the rest of my medical books, which I gave some years ago to the Boston Medical Library.

Believe me, Dear Sir,

Very truly and gratefully yours,

OLIVER WENDELL HOLMES.

The Hon. JOHN M. CREED,  
Sydney.

## MEDICAL ORTHOGRAPHY.

In an editorial article on the spelling of medical words, the *Medical News*, after calling attention to the tendency, especially in America, to simplify the spelling of certain words, and the dislike of the "Umlaut" and conjoined vowels, announces that the following rules have been adopted by the staff and its proof-readers :

(1) The English equivalent of the Greek  $\alpha$  (as in *παῖς*, etc.) will be *e* instead of the elder form *æ*. For example: Hemorrhage, Hematoma, Hemorrhoids, Anesthesia, Anesthetic, Gynecology, Anemia, Pyemia, Septicæmia, Etiology, Orthopedic, Pediatric.

(2) The Greek  $\alpha$  will be represented by *e*, instead of *æ*. For example: Edema, Esophagus, Cecum, Homeopathy, Gonorrhæa, Otorrhea, Apnea, Dyspnea.

(3) Liter, Center, Meter, Fiber, etc, will be so written. (Chancere is correct — for a special reason.)

(4) Gram, Previa, Precordia, Fetus, Feter, Fetid, Licorice, Dram, Labor, Rigor, Color, Gluteus, Gluteal, Ozena, Rachitis, Rachialgia, etc., are here properly written.

(5) Lencomaine and Ptomaine should be written with the diæresis.

(6) Unless we are brave enough to do without authorities, we shall have to submit somewhat longer to Casarean, Rhythm, Nevus, Fraumbesia, Amœba, Pharmacoœia.

In medical words there is generally no true etymology. They did not grow out of the Greek, but the Greek words were seized upon to serve as symbols and aids in forming new words, as it were with malice prepense, and often with a laughable ignorance of or indifference to the roots and laws of word-formation.

## SULPHURING OR BLEACHING DRIED FRUIT.

DR. JOEL W. SMITH, in a paper on this subject,<sup>1</sup> points out the dangers of the process.

As fresh fruit is not always obtainable, various methods for preserving it are in use, drying being one of the oldest and best for many fruits. Sometime ago sun or air drying was the only method for market. Then it was found that more rapid drying by artificial heat, with or without the addition of sugar, was a cleaner method, safer against fermentation and decay, retained the flavor better, and the fruit was also lighter colored than when sun or air dried. The present evaporators are only an enlargement of the idea of such more rapid drying, while canning consists in the exclusion of the microörganic germs of fermentation.

It is about fifteen years since the sulphuring or bleaching dried fruit began. At first only the uniform light color was sought, as in apples, pears, etc., but for some years past nearly all of the large evaporating establishments have "sulphured" all kinds of fruits and some vegetables, and now much of the California sun-dried fruit for market is also treated in the same manner. The light color, especially of apples, early attracted attention, thus materially increasing the price of such fruit. Fruit so treated is said to dry more readily. While the apparent change is only in color there is a loss of the natural fruit flavor, even by the most careful sulphuring.

The bleaching process is the result of the action of sulphurous acid.

Investigations have proved the presence of sulphate of zinc in all samples of fruit where zinc-surfaced trays were used to hold the sulphured fruit while drying.

The advantages claimed are that sulphured fruit dries quicker, looks better, keeps better, and sells better. It makes ripe, unripe, and poor fruit look alike. The slightly yellowish-brown color of unbleached dried fruit is an evidence of ripeness, good quality, and proper drying. The more rapid the drying the lighter will be the color, and the fruit will keep well if at once properly excluded from the air.

## THERAPEUTIC NOTES.

CREOLIN FOR DYSENTERY. — Dr. E. W. Watson<sup>2</sup> reports that in several cases of dysentery, serous diarrhoea and summer complaint, very good results were obtained by large enemata of creolin, one drachm to a pint of water.

A CHEAP DISINFECTANT.<sup>3</sup> — The nitrate of lead is the cheapest disinfectant known that fulfils its intent. It does not, however, prevent putrefaction. The chloride of lead is much more effective in all directions. It is made by dissolving a small teaspoonful of nitrate of lead in a pint of boiling water; then dissolve two full teaspoonfuls of common salt in eight quarts of water. When both are thoroughly dissolved, pour the two mixtures together, and when the sediment has settled you have two gallons of clear fluid, which is the saturated solution of the chloride of lead. A pound of nitrate will make several barrels of the liquid. The nitrate of lead costs from eighteen to twenty-five cents a pound at retail.

Deaths reported 4,324; under five years of age 2,215; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 1,309; consumption 371, acute lung diseases 202, diarrhoeal diseases 575, typhoid fever 111, diphtheria and croup 99, whooping-cough 38, scarlet fever 33, measles 18, cerebro-spinal meningitis 17, malarial fever 17, puerperal fever 3, erysipelas 1.

From whooping-cough Brooklyn 7, New York and Pittsburgh 6 each, Baltimore 5, Philadelphia and Milwaukee 4 each, Washington 2, Chicago, Boston, Cleveland and Lynn 1 each. From scarlet fever New York 14, Brooklyn 7, Chicago 4, Philadelphia and Milwaukee 3 each, Baltimore 2, Springfield 1 each. From measles New York 8, Chicago 6, Pittsburgh and Milwaukee 2 each. From cerebro-spinal meningitis Chicago 6, Brooklyn 4, Washington 3, New York, Philadelphia, Worcester and Lynn 1 each. From malarial fever New York 5, Baltimore, Nashville and Charleston 3 each, Philadelphia, Pittsburgh and Springfield 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,105,108, for the week ending August 1st, the death-rate was 19.6. Deaths reported 3,544; acute diseases of the respiratory organs (London) 173, diarrhoea 410, whooping-cough 12, diphtheria 46, measles 41, scarlet fever 31, fever 29.

The death-rates ranged from 9.9 in Brighton to 35.8 in Preston, Birmingham 17.8, Bradford 18.5, Hull 21.3, Leeds 23.0, Leicester 22.7, Liverpool 24.0, London 20.5, Manchester 17.9, Nottingham 12.3, Oldham 16.2, Sheffield 20.0, Sunderland 19.9, Wolverhampton 18.3.

In Edinburgh 15.5, Glasgow 18.6, Dublin 18.3.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,105,108, for the week ending August 8th, the death-rate was 19.1. Deaths reported 3,439; acute diseases of the respiratory organs (London) 171, diarrhoea 417, whooping-cough 18, measles 61, diphtheria 33, fever 20, small-pox (Leeds) 1.

The death-rates ranged from 12.1 in Derby to 34.9 in Preston, Birmingham 16.9, Bradford 14.1, Hull 16.3, Leeds 21.2, Leicester 21.2, Liverpool 20.2, London 20.2, Manchester 16.8, Nottingham 19.6, Sheffield 19.1, Sunderland 21.5.

In Edinburgh 12.3, Glasgow 19.3, Dublin 16.5.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 15, 1891, TO AUGUST 21, 1891.

Lieutenant-Colonel JOSEPH C. BAILEY, assistant medical purveyor, granted one month ordinary leave, in extension of sick leave.

CHARLES M. GANDY, assistant surgeon U. S. Army, will, upon the final adjournment of the Army Medical Board, resume his leave of absence.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 22, 1891.

W. R. DuBose, passed assistant surgeon, ordered to duty at Naval Academy, Annapolis.

G. E. H. HARMON, surgeon, detached from Naval Academy, Annapolis, and wait orders.

HOWARD WELLS, surgeon, ordered for temporary duty at Naval Station, New London.

A. A. HOEHLING, medical inspector, J. B. PARKER, surgeon, O. D. NORTON, passed assistant surgeon, ordered to Naval Academy, Annapolis, September 3d, to examine physically, candidates for admission to the Naval Academy.

## DEATHS.

GEORGE HINCKLEY LYMAN, M.D. (Febr. 1843), M.M.S.S., died in London, August 19th.

JOSEPH G. S. HITCHCOCK, M.D. (Harv., 1850), M.M.S.S., formerly of Foxborough, died at Clarendon Hills, August 23d, aged sixty-eight.

IRAM H. ATWATER, M.D. (Vt., 1851), of Burlington, Vt., died August 19th, aged sixty-three. He was for several years Physician to the Mary Fletcher Hospital, Instructor in Obstetrics at the University of Vermont, Health-Officer of Burlington, and Commissioner of the Insane.

## BOOKS AND PAMPHLETS RECEIVED.

Trichina Spiralis. By Dr. H. M. Whelpley, St. Louis.

Hernia in Infancy, and its Treatment. By W. B. De Garmo, M.D. Reprint. 1891.

Second Report of the Superintendent of the Johns Hopkins Hospital, for the year ending January 31, 1891.

Du Paludisme et de Son Hématozoaire. Par A. Laveran, Professeur à l'Ecole du Val-de-Grâce, etc. Paris: G. Masson. 1891.

Eleventh Annual Report of the State Board of Health of New York. Transmitted to the Legislature, February 20, 1891. Two volumes.

Injury to the Thoracic Duct, with an Unique and Inevitable Death by Inanition. By Alvin Feyer, M.D., Cleveland, O. Reprint. 1891.

The Association of American Anatomists, History, Constitution, Membership, and the titles and abstracts of papers, for the years 1888, 1889, 1890.

Report on Cholera in Europe and India. By Edward O. Shakespeare, A.M., M.D., Ph.D., United States Commissioner, Washington: Government Printing Office. 1890.

Leçons de Thérapeutique. Par Georges Hayem, professeur de thérapeutique et de matière médicale à la Faculté de médecine de Paris, etc. 3<sup>e</sup> série, 1 volume in 8. Paris: G. Masson. 1891.

Index Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Vol. xii. Regehr-Shuttleworth. Washington: Government Printing Office. 1891.

The Status of the Hydrochlorate of Cocaine in Minor Surgery, as based upon the Experience of Philadelphia Physicians. By Lewis H. Adler, Jr., M.D. Detroit: George S. Davis. Reprint. 1891.

The Physiology and Hygiene of Study During the Developmental Period, with Especial Reference to the Public Schools of Sacramento. By Wallace A. Briggs, M.D., Sacramento, Cal. Reprint. 1891.

Diphtheritic Paralysis. Normal Liquid Ergot in Enuresis Nocturna. Report of a Case of a Dissolving Anæsthetic: Euphonia and Death. Cocaine as a Local Anæsthetic in Cases Requiring Amputation of the Inguis, with a Report of Fifty such Operations in which the Drug was employed. By Lewis H. Adler, Jr., M.D., Philadelphia. Reprints. 1889, 1890, 1891.

## Address.

COMMON SENSE IN MEDICINE.<sup>1</sup>

BY S. C. GORDON, M. D., PORTLAND, ME.

A CELEBRATED bishop, president of one of the most noted universities of this country, said to his class in divinity: "There are three things necessary for making a successful minister of the Gospel: first, a thorough, liberal education; second, the grace of God; third, common sense. The first may be obtained by earnest, diligent application to study; the second by prayerful intercession at the throne of grace, with a sincere desire for purity of heart; but unless you have the third born in you, may the Lord have mercy on your souls and the souls of your congregation."

While common sense is an absolute necessity for any profession or vocation, I know of no one where it is more necessary or important than in the study and practice of medicine. If I were asked to define the terms common sense, it might be difficult; but it will be sufficient for our purpose, at the time, to say that it consists in applying rational, simple rules of construction to the various theories of medical science, adopting and practising what can be measured by such rules, and rejecting those that are at plain variance and antagonism with them.

In the discussion of common sense in its application to medicine, I propose to briefly touch the following topics:

- (1) Who should study medicine?
- (2) What should be the preparation for the study of medicine?
- (3) What are the best methods at the present day for the most profitable pursuit of the study?
- (4) What are the essentials for a successful career in the practice of the profession?

The question, who shall or ought to study medicine? is an exceedingly difficult one to answer satisfactorily, in a country like ours, where every young man may legitimately and properly aspire to any position in life, even to be president of the republic. There can, therefore, be no absolute standard for or limit to applicants for medical honors. Our country is not yet old enough or conservative enough for young men to follow the vocations of their fathers to the same extent as in European countries. Hence, each one selects for himself whatever his inclination or judgment prompts. In this way we undoubtedly secure better men, as a rule, in the ranks of the profession. The so-called self-made men are trained in the rugged school of necessity, and, therefore, become familiar with practical facts, which constitute what we so well know as a knowledge of the world. Such men are usually better prepared (with proper education) to deduce from scientific theories the principles which become the foundation for the successful practice of the profession. In short, the common sense acquired in early life aids them very materially in the strictly technical studies.

As regards the second question (what should be the preparatory education for the study of medicine?), we find more or less difference of opinion among the best minds. A recent president of the British Medical Association, in his annual address, says, "Education is just now in a state of fermentation." The old curri-

culum of our colleges is fast breaking up, being revised and adapted to the practical age in which we live. While it may be desirable that a young man, entering the so-called liberal professions, should have all the training of a so-called liberal education, to be derived from the strictly classical course of the college or university, I believe, with many others, that the time spent in a four-years' course under the old curriculum of most New England colleges, was a great waste of time.

The demands of modern science are such that one must neglect many more important elementary studies or sacrifice a portion of the ancient languages and higher mathematics. It is true that most colleges at present do not require the amount of Latin and Greek and higher mathematics, formerly made obligatory; and elective courses are becoming more general throughout the country. American institutions are more in accord with the practical demands of the age.

The terms used in *materia medica*, embracing the writing of prescriptions, etc., as well as those in anatomy, require a moderate amount of Latin only; while the nomenclature of diseases is much more readily comprehended, and its study greatly facilitated by an equal knowledge of Greek. Beyond this, I think, the student of medicine should not be required to pass an examination. German and French are far more important to the practitioner, who would be *au courant* with the literature of the profession—in fact, they are indispensable to medical investigation. How many men in the profession who are ten years out of the classics can with ease read any once familiar paragraph from the standard text-book of Latin or Greek? My impression is that only a very small percentage would care to submit themselves to an examination. In too many instances, I fear the original rendering was done by the ever faithful "pony," which did such good service under the desk during recitation; and had the same passage been given him the next day, the absence of the "pony" would have required him to take a "dead." Such knowledge is altogether too costly, and does not even give the mental discipline which we are taught to believe it does. The time could be much more profitably spent in some of the other elementary studies, for which he would have more practical use, and from which he could derive as much "habits of study" and discipline. Physics, chemistry and elementary biology in their application to practical medicine, would not only be far more interesting, but directly in line of future work. Certainly, to one who could decide early in life as to the choice of the profession of medicine, the latter course would, in my opinion, be more in accord with common sense. I am well aware that many other things, aside from the mere curriculum, are to be obtained in the ordinary college course. I am also well aware that faithful, diligent devotion to study during such a course may make a much more polished and accomplished man for any position in life; but daily observation teaches us all that it too often makes only a man educated in books, with but little practical knowledge that he ever uses.

I would not be understood as in any manner decrying or belittling a liberal education, as a preparation to the study of medicine; but I do wish to emphasize the point that an A. B. is by no means an absolute guarantee that its possessor has had the proper preliminary training for the successful prosecution of the study.

<sup>1</sup> Annual oration delivered before the Maine Medical Association, June 10, 1891.

I would encourage the elective course more; and I am glad to know that most colleges are now adopting this plan. In such cases the student can, during his last year, select those things which bear directly upon his future work. I would not so widely separate the classical from the professional course.

It seems to me that the schools of technology are becoming one of the most valuable means of practical instruction for men of all vocations. The scientific school at Yale offers a very valuable curriculum to one who has his choice of a profession clearly defined. If medicine be the one selected, he can enter upon the elementary studies of the profession in such a way as to become practically familiar with them.

Botany, physics, chemistry and biology in general are taught experimentally. The student is compelled to literally "take off his coat," and go to work to learn the fundamental principles, in the only true way they can be learned, by object lessons,—the kindergarten system developed to the capacity of a man's comprehension. At the same time he is acquiring theories by study of the best text-books and such didactic instruction as may aid him in properly understanding the daily routine of his work. But he must learn his botany by actual dissection of plants, as he learns his anatomy by dissection of the animal creation; his chemistry by laboratory work; his physiology by vivisection and other familiar experiments. These become the proper foundation upon which to build the superstructure of a finished education. In short, this preparatory course simply teaches him how to study. As between this and the old college curriculum, embracing so much of ancient languages and higher mathematics, I am fully persuaded that the experimental course is the better.

I am well aware that there are two sides to this matter, and honest and wise men differ as to the comparative merits; yet for the average student, I believe we will turn out from our medical schools better workers in the profession, if they have been trained in the working schools. It may be said, on the one hand, that one's education should be upon the broadest possible basis, embracing a full knowledge of the world and mankind in general, for it is by individual contact and association that success is attained; that the man who has had the broadest, most liberal education is the best fitted for any special work. I grant this, and would not by any means ignore the necessity for a proper classical course as a preliminary to the study of any profession, especially ours. But as life is too short for one to know much of any one thing I am fully convinced that we can improve on the old methods.

In my mind one of the most typical ideal "doctors" that novelists describe is that of Lydgate in George Eliott's "Middlemarch." This class of writers are not usually happy in descriptions of members of our profession; but in this instance the character is well sustained from first to last. He is a common-sense man throughout his varied career, at least, so far as his professional aims, ambitions, and relations with his patients and professional brethren are concerned. The author makes one of the characters say of him, "I do not want a doctor who knows nothing but his profession. He does not interest or benefit me. He is run in too narrow a mould, and not being familiar with matters outside of his profession, cannot bring to bear the best means for the alleviation of human ills."

The every-day experience of each man in the profession must convince him how true this is. "Canst thou minister to a mind diseased?" is by no means an infrequent question we are called upon to answer; and he answers it best who has made himself master of all the emotions of which the human soul is capable. "To unlock the secrets of the human soul" becomes one of the problems that the wise physician is required to solve. He must stand as minister, lawyer and friend, as well as medical adviser. His knowledge must therefore be as boundless as science and his wisdom as profound as the depths. For such a profession no limit can be placed to even a preparatory education.

What are the best methods for the study of medicine? For many years I have believed the general plan of studying and teaching medicine was radically wrong—contrary to common sense, and in many respects, unlike the study of any other profession or vocation. This radical defect consists in too much theory and too little practical knowledge. Class after class is graduated and commences practice, with little if any familiarity with disease or practical application of remedies for its relief or cure. They study text-books and hear didactic lectures. In too many schools this is largely the extent to which the sense of sight and hearing are used. The early use of the sense of sight, for diagnostic purposes, at the bedside or at dispensaries and the operating amphitheatre, has been discouraged, and students are told that they must not attempt to study disease in the patient or become familiar with the technique of surgery, until they are familiar with the theory by didactic lectures and text-books. To use a paradoxical illustration, "they must not go near the water until they have learned to swim."

Diagnosis, like confidence, is a plant of slow growth, and it is only by long years of clinical study that one becomes an expert. I would have the student of medicine embrace every opportunity to see any case of medical or surgical interest from the earliest days of his student life. It is through the sense of sight that we become familiar with the chief diagnostic points of some of the most obscure diseases. "The color of the face, eyes, skin, lips; the expression, posture, movements, breathing, nutrition, should be taken in at a glance. Practice compels all physicians, if successful, continually to do these things, in order to learn; but training cannot begin too early," says one of our leading journals.

The skilful diagnostician should be able rapidly to enumerate the points in physiognomy and physical structure, just as a painter selects the salient points in a landscape for his picture. The brilliant men in our profession are those who have cultivated the special senses to the highest degree. Such a man unconsciously makes a diagnosis without being able, in many instances, to convey to another his reasons for the faith that is in him.

The same rule applies to all the other senses as to sight. The touch especially becomes a most important element in surgical diagnosis. Long practice enables the surgeon or gynecologist to determine, almost as accurately as by sight, the pathology of a part affected. Certainly no student can begin the education of this sense too early. Mr. Tait, in his work on "Methods in Diagnosis," says: "It is absolutely impossible for me to convey by any kind of description, how I can tell by the touch an inflamed vaginal nervous surface from one that is healthy. Neither can I de-

scribe the feeling that an everted surface of the cervix uteri gives to me, which declares the existence of endometritis; but the educated finger-tip does it."

The numberless instances where it becomes necessary to decide, in relation to pregnancy in the early stages, the difference between a retroverted uterus and a myoma, between a cyst and a hæmatocele, these and a multitude of other conditions require constant practice for years. The sense of hearing needs other training than listening to a poor compilation of a musty text-book. It needs careful and frequent drills in all that pertains to diseases of heart and lungs before one can carefully and distinctly differentiate the various sounds, both normal and abnormal. To be able to analyze and clearly define the pathological symptoms, requires years of practice. At first it is a chaos; but order will eventually come out of it by systematic labor with one's own ears. It cannot begin too early. No amount of theory derived from books or didactic lectures can take the place of the clinical study.

There is no orator so gifted or teacher so skilled as to convey to the most brilliant student the sounds to be heard by the direct application of his own ear to the chest. The sound of a patient's voice also becomes a key-note to many important points in diagnosis.

The sense of smell can be educated to the highest degree, not only to detect unsanitary conditions, but absolute pathological changes. I believe this sense has been too much neglected.

In view, then, of the absolute necessity for personal contact with the patient in order to become expert in diagnosis, I am sure the demands of the day are for a radical change in the methods of teaching and learning medicine. For many years I have believed that the didactic method was doomed to pass away. Most of such instruction has been and is yet, simply a repetition of what can be found in the standard text-books, oftentimes delivered in an uninteresting and uninteresting manner. Few men are interesting teachers; and if the student has had the preparatory education which we claim he should have, he can read the text-book much more understandingly than if he listened to a dry, dull lecture. I admit that now and then we find a teacher who has a higher and nobler conception of what his duty is, as an instructor. His teaching consists in impressing upon his hearers the results of his own personal experience, in the application of general principles to every-day work. Such teaching is fresh from the fountain, and the pupil is refreshed thereby. How frequently I hear young men in the profession say, "I remember literally nothing of the lectures. I got little or nothing out of them. I was obliged to listen to and take notes upon them, simply that I might pass an examination and receive my degree. The only things that made any impression upon me and from which I derived any good was by illustration clinically, or by well-executed drawings or sections upon the living animal or cadaver."

"I was ever thus from childhood's hour." We learn most through the medium of our special senses, brought to hear upon the subject under consideration. Professor Dwight, of Harvard, said to his pupils in anatomy: "I do not propose to lecture to you from the book; you can read and get that for yourselves, and in a much better way than I can give it to you. I propose to give you what cannot be found in the text-books." Professor Senn, of Chicago, said, in substance: "I do not flatter myself that I can entertain

you in quoting from the text-books on surgery. The great writers who are worthy to be quoted from have enunciated the external principles of surgery in a manner far more eloquent than any language of mine; but I can give you the result of my own daily and hourly work, based, I trust, on those principles, but modified by the accumulated experience of years."

It seems to me almost an insult to the intelligence of the properly-educated student to spend an hour repeating stale and obvious facts taken from a text-book which he can read and digest as well as I. The fundamental principles of medicine must to a great extent be learned from standard books, to be sure; and I would not ignore the value of competent teachers as helps to a proper understanding of many things which would be difficult of comprehension without such aids; but I would limit such teachers to hearing recitations, and thus coming in direct contact with the student, who should be compelled to do the chief part of the work. I have hoped for many years to see this reform in medical education, and I am gratified to find a school, based upon this plan, has already been organized in Columbus, Ohio. Recitations, laboratory work, dissections for learning anatomy, and clinical instruction constitute the essentials of this new plan of study. Professor Drysdale is totally left out of any such institution as this.

The *Medical Record* of a recent date says: "It is reported on good authority that the University Medical College of this city will hereafter abandon, in large measure, the didactic lecture, and teach its students by recitation. Such a change, if made, will be the most important and radical improvement in the system of medical teaching that has been undertaken for many a day. We have long argued in favor of abolishing the didactic lecture, as being an absurd relic of an effete and ancient system of instruction. There has never been any valid defence offered in its favor, except that the recitation method is more laborious, more expensive, and one which perhaps adds less dignity to the professorial chair. Such things, however, are not to be considered in searching for the best method of teaching. It is the student's good which must first be looked after, and it is by the drilling and marking of the recitation that this good is obtained."

Other schools are already in contemplation, based upon similar principles, and the medical teachers of this and other countries are fast waking up to the idea that to learn medicine properly, one must begin at the foundation, and work up by his efforts, using the practical working tools of the profession.

One of the most eminent teachers of the world, Professor Gairdner of Glasgow, in seconding a vote of thanks to the President of the British Medical Association last year, at Birmingham, among other things of equal importance said: "I think medical education ought to be organized upon the principle that it shall be real, as Faraday put it, and not nominal; that every part of it shall be an *education into things* and not *into words about things*, and that is the great difficulty, [*italics mine*]. The greatest benefit that could be done by the extension of the science in the early years, would be that the mind of the young man or boy would be opened out in the right direction, that whereas at present his education is to a great extent instruction in words telling about things, it would be instruction in the things themselves. . . . There will education cease to be the lop-sided thing it is, and will be

come much more broad and general, and not a smattering, but an education in reality."

This is the spirit that prevails at the present day among the most advanced teachers in all departments of science and art, a positive education and not mere words. The old preceptor system, where the student recited his anatomy as he drove about over the country roads and became familiar with the various types of disease that came under his notice, had its advantages in many respects over a mere instruction in words, coming from the most distinguished didactic lecture, with the clinical instruction left out. Men educated under such common-sense methods were better prepared to fulfil the great object of professional life (the cure of disease) than one who could take much higher rank in an examination. It is impossible to pump a man full of medical science, and make a reliable, safe, practical common-sense practitioner. When he attempts to put his theories into practice, they do not seem to fit the case. The actual case is widely different from his theoretical one that he had read about in the text-book, or the one his professor had talked to him about. It is probably within the experience of all of us that for the first few years of our professional life we found more new cases of disease than we did for many, many years after—cases that had not been described, and all were nearly ready to astonish the medical world by some of these brilliant discoveries. Fortunately for our reputation we did not always act upon our first impulse. Time and study of our cases obliterated the discrepancies, and we were wiser and better ever after. Had our medical teaching been more clinical and less didactic, and, therefore, theoretical, we should have made less discoveries.

### SOME POINTS REGARDING GENERAL PARALYSIS.<sup>1</sup>

BY C. F. FOLSON, M.D.

On the many divisions of general paralysis into several clinical types, all of them naturally more or less arbitrary, I know no other so satisfactory as Meyner's eight.<sup>2</sup>

(1) Simple progressive dementia, with the usual progressive motor impairment which accompanies it.

(2) With delusions of grandeur and with marked motor disturbances, which appear simultaneously and are progressive. The mental state is usually of exaltation, but there may be depression.

(3) Of the same type as the last, but failing its steadily progressive character, that is, with remissions.

(4) Cases in which the characteristic exaltation and grand delusions reach such an astounding height that manifest motor symptoms are looked for with confidence from day to day, and yet may not appear even for a year, any slight incoordination naturally being obscured by the general muscular disturbance. Meanwhile there may be such an improvement as to simulate a recovery.

(5) A very rare form, with alternate symptoms of exaltation and depression.

(6) With early furious delirium, painful hallucinations, confusion and incoherence somewhat resembling acute delirium.

(7) In which the characteristic indications appear secondary to other forms of insanity, for instance, after paranoia or melancholia.

(8) The combined form, with sclerosis in the whole cerebro-spinal tract, the symptoms of tabes or spastic paralysis predominating, according as the posterior or lateral columns of the spinal cord are chiefly involved. The ascending type, in which the cord is first affected, is rare. Optic neuritis, ending in atrophy and paralysis, especially of the ocular muscles, may precede marked mental symptoms.

In Paris, in 1874, and chiefly by Sander in Berlin, in 1876, attention was called to a period in general paralysis in which there are vague signs of mental failure for a varying length of time, perhaps for several years, antedating the pronounced symptoms. This early stage is most marked in Meyner's first class, the demented type, to which the recent great increase in general paralysis belongs.

To the question, What is the pathological basis of general paralysis? the answer is not easy. The disease has been called chronic meningo-encephalitis, chronic diffuse periencephalitis, and, perhaps best of all, chronic diffuse cortical encephalitis, whether primarily interstitial or parenchymatous, ending in greater atrophy than occurs in any other form of insanity. The gross lesions correspond to these various terms and involve others by extension of inflammatory or degenerative or atrophic processes. To the naked eye the appearances may be of the most intense meningo-encephalitis, or in various degrees down to such simple atrophy as may be seen in many wasting diseases. The essential microscopic changes found in the brain, are chiefly in the cortex, and have been well described by Mendel:

(1) Increase of nuclei and new cell-formation, some nuclei small, some large, and with such varying reactions to coloring agents as to suggest dissimilarity of origin. The stellate or "spider" cells are increased in the upper layer of the cortex, where some may be normally found, and extend to lower layers, as is not the case in normal brains; they, too, may be several times the usual size and also push through the white substance to the ependyma of the ventricles; proliferation of neuroglia or connective tissue, and in time sclerosis of the cortex, which involves the medullary substance also, in a greater or less degree.

(2) The larger blood-vessels may or may not be atheromatous. In the capillaries there is an increase of nuclei in the walls, with thickening and hyaloid degeneration.

(3) In the nerve-cells, the ganglion cells, granular and fatty degeneration of protoplasm, sclerosis, atrophy.

(4) Atrophy and final disappearance of the nerve-fibres, not limited to the cortex, and found in other brain diseases also, senile dementia and epilepsy for instance.

(5) Focal lesions of the most various kinds, and degenerative changes in the spinal cord, the several forms of sclerosis and myelitis.<sup>3</sup>

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Therapeutics, General Medical Society, May 20, 1891.

<sup>2</sup> *Journal of Angewandte Psychiatrie*, Wien, 1890, Braumüller.

<sup>3</sup> Mendel, Berlin Congress, 1890. These points were illustrated by plates which cannot be reproduced.

The post-syphilitic cases, with a previous history of syphilis not recent, those not only not benefited by iodides and mercury, but usually debilitated and injured by them, may exhibit post-mortem the same microscopic changes as those in which there is no ascertained evidence of syphilis. In paralytic dementia, with a recent history of syphilis also, and with marked indications of specific disease, where anti-syphilitic remedies avail to produce such an amelioration of symptoms as to simulate a cure at least for a time, the same diffuse cortical changes may be found at the autopsy-points, which, in making and in verifying diagnoses should be borne in mind, as well as the facts that there are degenerative changes in the brain secondary to gross syphilitic lesions, which do not constitute general paralysis, and that the several types of general paralysis and other conditions of cerebral atrophy exhibit post-mortem appearances which may so gradually shade off into each other as to make the analogy very close.

In senile and chronic simple insanity, the atrophy of the nerve-fibres is primary. In paralytic dementia, the essential process, according to Obersteiner, is a diffuse primary sclerosis of the cortex, which leads to atrophy. It appears in the frontal lobes first. The sclerosis is preceded by a condition of irritation which seems to justify the expression, chronic periencephalitis, but the brain coverings play only a secondary part. In very acute cases, in which we are enabled to recognize an early stage in the diseased processes, we are struck with the quantity of lymphoid bodies which surround the blood-vessels throughout the whole brain. These leucocytes probably migrate out of the blood and pass through the neuroglia or ground tissue of the cortex as wandering cells before being changed into stellate or "spider" cells. Perhaps also the stellate cells, normally present in the cortex, provide further material for proliferation. It is in the overgrowth of these cells belonging to the connective tissue that we have to look for the cause of the sclerosis. So soon as these cells occupy so much space as to surround and press upon the normal nerve-tissue cells, the latter atrophy. The result of this process is seen in old-standing cases, not only in the degenerated nerve-cells, but also in the remarkable diminution in the quantity of medullated fibres. This disappearance of medullated fibres advances from the periphery inwards; so that, as a rule, the outermost layer of tangential fibres is most affected, whereas in senile atrophy the decrease in the number of fibres affects all the layers equally. The convolutions most constantly and distinctly affected are those on the orbital surface of the frontal lobe, especially on the side of the great longitudinal fissure; next, those of the island of Reil and the left inferior frontal convolution. The other frontal convolutions, the gyrus fornicatus, the paracentral, superior temporal and ascending parietal convolutions are often diseased to a similar extent. All other parts of the cortex are, it is supposed, affected in a less degree only, or, in the case of the occipital lobe, it may be scarcely at all. A decrease in the number of fibres may be met with in other conditions besides paralytic dementia, in senile atrophy and long-standing epilepsy, for example. The changes in the structure of the cerebral cortex to be seen in paralytic dementia assume many forms, however, hence the description of pathologists differ widely one from another.<sup>4</sup>

<sup>4</sup> Obersteiner (Hill's translation) and Tuzcek.

Can it be that, as there are so many clinical forms of general paralysis, there may be also more than one from a pathological point of view?

While it cannot be said that any particular morbid changes in the brain are singly characteristic of general paralysis, inasmuch as they appear in other degenerative cerebral diseases, yet the whole group involving chiefly its anterior and antero-lateral portions, the psychic and psycho-motor tract, and resulting in such marked final atrophy, is found in no other condition. Indeed, the trained pathologist has been able to diagnose as general paralysis, after death by suicide, what had been supposed during life to be melancholia, distinct motor symptoms not having been observed. The fact is interesting, too, that healthy and diseased cells and nerve-fibres are seen side by side, so that the early symptoms do not constitute a paralysis but a cortical ataxia, a motor intelligence-disturbance as Obersteiner well says, on the one hand and on the psychic side mental failure due to defective association of ideas through greater or less affection of the association-fibres in the cortex. Farther than that we can scarcely yet be said to know much about the relations of pathological conditions to abnormal mental manifestations in general paralysis, except so far as the final atrophy explains the intellectual and physical decay.

After this somewhat long definition of what is meant by the term general paralysis, I will not detain you with a discussion of the difficulties in the diagnosis of the disease in its obscure though pronounced forms, including the exclusion of cerebral tumors of the anterior lobes; cerebral diffuse sclerosis; intracranial hæmorrhage, embolism or thrombosis; phlebitis of the venous sinuses; cerebral syphilis; premature senile decay and primary atrophy of the brain, which may both be attended with epileptiform or apoplectiform convulsions; acute mania with extravagant delusions; primary dementia; alcoholic dementia or mania; chronic alcoholism; the slow atrophy and degeneration of the brain in one form of primary insanity; symptoms of brain failure in chronic nephritis or from impaired circulation in heart disease; lead-poisoning; bromidism. All these conditions may simulate general paralysis, and may make the diagnosis difficult, or, for a while, impossible. The grouping of the symptoms, no one of which may, at the time, be typical, and the symmetrical character of the mental and physical deterioration, are the determining points in an obscure case.

In the study of the early stage of general paralysis it is convenient to divide it into first a prodromal, and second, a later or initial period. The symptoms of the prodromal stage, so to speak, are vague and indeterminate, very much resembling those of cerebral asthenia from any cause, but usually without the so-called neurotic element. Now and then, but rarely, associated with it, we see quickened wits, blunted sense and moral sense, with slight exhilaration. This stage is thought by Meynert to depend upon cerebral vascular disturbances which are functional and curable, and to precede the slight organic changes which characterize the next or initial stage. I think that as a rule, the subjective symptoms are so much less in general paralysis than in cerebral neurasthenia that medical treatment is not thought by the family to be important and the patient regards himself perhaps as only tired, so that it is for the functional cases, for the most part, that the physi-

cian is consulted, or for such symptoms as depend upon definite ascertainable conditions of disease. In functional disorders the cerebral vaso-motor disturbances are more constant and pronounced; they are conspicuously observed and dwelt upon by the patient himself, while the prodromal indications of general paralysis seem trivial or are unobserved by him and attract the attention, if of any one, of his close associates. It is chiefly by exclusion, if at all, that the prodromal period of general paralysis can be detected or at least suspected. After the diagnosis has been narrowed to a question between general paralysis and cerebral exhaustion, a previous history of syphilis and the age of the patient are most important factors. If under the age of thirty, general paralysis, except as the result of comparatively recent syphilis, can, as a rule, be excluded. If over fifty-five, some other condition than general paralysis is more probable, provided there has been no syphilis, and Mendel's estimate seems to me correct, that it is an antecedent in at least seventy-five per cent. of all cases.

I have usually found when I had opportunities to investigate, that in the history of general paralysis the prodromal period, although not at the time considered important as such, is remembered as having existed. But, of the very large number of cases which I have seen in the last ten years presenting symptoms of cerebral asthenia or general neurasthenia, I have not found, even in the many who neglected treatment, a single case of general paralysis follow; and in the three or four cases where I ventured to provisionally make that diagnosis, either I was mistaken or a recovery followed with but very little treatment but rest. Of numerous cases with the symptoms of cerebral hyperemia which are so common in brain-tire from over-strain, I have not seen one develop into general paralysis, nor have I known a case of general paralysis with such antecedents. In the prodromal period the best that we can do, until our means of diagnosis vastly improve, is to indicate a certain danger signal by which to warn our patients.

When to vaso-motor indications, whether slight or not, symmetrical motor symptoms are added, the initial stage begins, and its appearance is most insidious. There is a little general muscular weakness, with some failure in concentration and adjusting skill. The occasional lapses from a former standard of living, of self-respect, and perhaps decency or honor, if they occur, are regarded as ethical rather than as requiring medical advice. The inexplicable change in personality, in character and conduct, is simply not explained. The diminished physical power or endurance, is thought fatigue. The muscular incoordination and embarrassment of speech are so slight as to rarely admit of easy detection. The initial signs of general paralysis are of brain failure. They may be recognized in a large proportion of cases, at least in those persons whose muscles and brains are highly organized. In professional and business men a less degree of impairment is recognizable than in mechanics; in routine employments a large degree of deterioration may be unnoticed. In day-laborers an early diagnosis is simply impossible.

The initial indications are recognized perhaps as much from the peculiar quality of the mental impairment, difficult to describe, as from its degree. The physical symptoms may be so slight as not to be appreciated for a long time, except as an unusual sense of

weariness on exertion, which may also show itself after long talking or reading in a slight failure in putting words and ideas and sentences together. Commonly there is loss of flesh, slight, moderate or excessive. Very great or disproportionate loss of muscular power, especially in the legs, I have found to be due to a complicating peripheral neuritis. Even the expression of the face and the general appearance of the patient are often characteristic. There may or may not be slight confusion, a sense of fulness in the head, headache, insomnia. Except for unusual physical as well as mental fatigue following effort, the patient may feel well and not complain of anything. There may be no indication from the eyes or the reflexes so early; the muscular tremor is, as a rule, less than in functional nervous disorders; the speech may be not noticeably affected to the family, and may be only like that of a person with lips chilled by the frost or slightly under the influence of wine. It may be necessary to have the patient read or copy several pages, or be under observation for several days before the defect in the use of the muscles is manifested. His impaired ability to adjust himself to his environment may be detected only by testing him in a new place or by occupying him in unaccustomed ways. The distinguishing feature of this stage of general paralysis is the fact that the change observed consists in a symmetrical deterioration, which is distinctly motor as well as psychic, and, as in all diseases in which a vaso-motor element is prominent, varies from time to time, and may disappear, at least temporarily, by complete rest, just as excitement, fatigue, alcohol and vaso-motor stimulants bring out the symptoms more markedly. The clinical history of the initial period is so lacking in sharp definition and clear description, in contrast to the striking picture of typical general paralysis in its advanced stage, that it is all the more easily mistaken for something else.

In a doubtful case, a previous history of syphilis, naturally, very much increases the probability of general paralysis; and I am satisfied that no one of the methods of treatment for the primary chancre, or its constitutional symptoms, even if in the hands of the most skilled specialist, secures immunity against cerebral syphilis or general paralysis later. In no case of syphilis, as I read the evidence, however treated, are we justified in saying to the patient that he is cured so far as a small chance of possible late manifestations in the brain and nervous system are concerned, at least not until after a long term of years. The chance may be small, but it is there. How far specific treatment in syphilis may diminish the chances of subsequent paralytic dementia, or modifies our prognosis in its prodromal and initial stages, is a question which there are now no better means of determining than the character of the relation of the one disease to the other.

While we may not accept Zeissl's dogma that once a syphilitic is always a syphilitic, that his corpse is a syphilitic corpse, and that if he revisits the earth he comes as a syphilitic ghost, or believe with another pessimist that one of the chances which every woman who marries must take in all social grades is that of her husband some time having some late manifestation of syphilis, it seems to me that the medical profession is not sufficiently cautious and conservative in its warning and advice regarding the dangers which are incurred in syphilis. If the risk is small, comparatively speaking, when the syphilis is wisely treated,

it still is greater than many men would take, in considering marriage for instance, if they were correctly informed. One man contents himself with one chance in two hundred; another with one in ten; and there are some matters in which others will not knowingly run any risk at all. We may formulate our opinions as to probabilities in syphilis as we like. We often cannot, when we would, prevent our patients from doing as they are inclined. We can, however, leave the responsibility for the tragedies of late syphilis where it belongs and thereby perhaps diminish the prevalence of syphilis more than by laws.

ination of the growth, and sent me the following report.

"Boston, August 11, 1890. The piece of tissue removed by Dr. Clark measured three centimetres in length, and one-half centimetre by one centimetre in thickness. [The tumor had been for some time in fifty per cent. alcohol, and had consequently shrunk somewhat.] The tissue was soft and friable. Microscopically it was made of medium and large-sized cells densely crowded together, with very little intercellular substance, giving the appearance of round-celled sarcoma."

My notes say;

September 29th (one month after last operation). No signs of return. The mucous membrane apparently everywhere normal. Nothing to show where either tumor was attached.

October 30th. Small rounded swelling (size of a pea) on left side of septum, near posterior edge. Mucous membrane over it, same in color as surrounding membrane. Nothing abnormal about the turbinated bodies.

November 17th. Growth on septum now the size of a large bean. Removed with wire snare. Very little hemorrhage.

November 28th. Piece the size of a pea (apparently a remnant of the last operation) removed.

December 17th. Slight irregularities on septum at the site of former growth.

February 5th. Still some thickening at site of growth (septum). No apparent increase since last observation.

March 17th. Small remnant of growth (size of pea) removed from the septum. The site was the same as that of the previous growth.

May 2d. Since the patient was last seen, another recurrence has appeared on the septum. This is about the size of a large bean. Removed with cold wire snare.

Dr. Greene has kindly examined the re-current growth removed from the septum on November 17th, and reports: "The specimen consisted of a soft, round piece of tissue somewhat smaller than the tip of the little finger. Microscopically, this tissue consisted mainly of large round cells, close together, and a few thin bands of fibrous tissue running through the growth. There were a few large blood-vessels, and occasionally a large gland lined with cylindrical epithelium. The appearance was that of a large round-celled sarcoma."

It would appear from my notes that the growth of the tumor was considerably more rapid in the six weeks preceding the second of May than previously. Whether this means that the growth has taken on greater malignancy or not, time will show. Of course the patient will have to be kept under observation, and further recurrence promptly treated.

Sarcoma of the nasal passage seems to be a comparatively rare affection. In his first volume of "A Treatise on Diseases of the Nose and Throat" (1889), Bosworth gives a brief *résumé* of forty-two cases, all that he could find reported up to that time. (This list does not include sarcoma of the naso-pharynx which is treated of in another chapter.) I have been able to find, besides these, the reports of six cases published since Bosworth made his list.

Heymann reports the case of a man, aged fifty-eight, subject to rapidly-recurring polypi, which finally be-

## SARCOMA OF THE NOSE; WITH REPORT OF A CASE.

BY J. PAYSON CLARK, M. D.

G. W., colored, thirty-five years of age, came to the dispensary in July, 1890, complaining of obstructions of the nose, especially of the left side. He had never had any trouble with his nose until three months before, when he began to have difficulty in breathing through the left nostril. This difficulty had increased until the left nostril was almost entirely occluded and the right was beginning to be obstructed.

On posterior rhinoscopy the left nostril was seen to be completely filled by a bluish-gray mass extending into the naso-pharynx and beyond the septum towards the right side of the pharynx. The origin of the growth was not perfectly clear, but it was apparently the middle turbinated bone. Anteriorly, in the left nostril, the growth could be seen far back, apparently arising from the middle turbinated.

I at first removed, with the cold wire snare, through the right nostril, the small piece which could be seen extending beyond the septum. In attempting to keep this piece in a fresh state for microscopic examination, it became so soft that it could not be satisfactorily examined.

I then attempted, under local anæsthesia (ten per cent solution of cocaine), to snare the growth. This was a somewhat difficult procedure, owing to the prominence of the lower turbinated body, and a projection from the septum above, which hindered the placing of the loop. Besides this, the tumor would bleed quite profusely at the slightest touch, so that after one unsuccessful attempt, nothing more could usually be done at that sitting. About two weeks later, after repeated unsuccessful attempts to get the loop in position, I finally managed to engage the growth in the snare and remove the larger part of it. The instrument used was Dr. Hooper's combined snare and excraser, the snare being turned slowly for fear of hemorrhage. The growth was so soft, however, that the loop cut through sooner than I expected. The bleeding, which was moderate, stopped very soon. The remainder of the growth shrank considerably, so that quite a clear view could be had of the posterior nares. This view disclosed the fact that there was also a small growth, of similar appearance, from the septum, near the posterior border. This growth was removed, together with the remains of the larger growth on the middle turbinated, in two more sittings, and the nostril was left perfectly clear.

Dr. E. M. Greene kindly made a microscopic exam-

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, May 20, 1891.

came complicated by a dense, sessile, grayish-black tumor of the septum, the size of a nut, attached by a large base. This growth, upon removal (by the galvano-cautery), proved to be a melanotic sarcoma. No recurrence one year after the operation.

Pascale reports the following case: Male, aged thirty-six, in whose left nostril, three months before, appeared an excrescence the size of a small bean (location not given), which in the course of a month increased so rapidly as to fill the whole nostril. It was removed, but quickly recurred, filling the nostril, and at the same time causing difficulty and pain in mastication. The growth finally involved the hard palate, causing a rounded, soft projection into the mouth, also conspicuous left-sided exophthalmia. The nose had lost its shape, and was bent to the right, so that the right nostril was occluded. Some of the growth projected out from the left nostril. The patient had had one hemorrhage, in which the blood came both from nose and mouth. The patient was operated on, and the left side of the upper jaw removed. The wound healed well, and there was no recurrence at the time of writing. The date of the operation was not given; but I judge that it was only a short time previous to the report.

Dr. Hooper reports two cases. The first, a man sixty-two years old, came to him complaining of occasional hemorrhage and obstructed breathing. The breathing through the left nostril had become gradually impeded, and for the previous six weeks no air had come through it. The growth was a smooth, reddish tumor, completely occluding the left nostril. The origin was the anterior inferior cartilagenous portion of the septum. The patient lived at a distance, and had not been heard from since the operation. The second case was also a man, aged sixty-five. The symptoms similar, though not so marked, as in the first case. The growth was situated in the anterior superior region of the cartilagenous portion of the septum. Four months after the operation there had been no hemorrhage and no sign of recurrence of the growth. In both cases pedicles were very small. Microscopic examination of the first growth showed it to be a fibro-sarcoma. The second was a myxo-sarcoma teleangiectoides. The operation in each case was done with the cold wire cauter.

There are only three cases of melano-sarcoma of the nose mentioned in literature. Lincoln's (reported by Bosworth), Heymann's (reported above) and Michael's. This case was a woman, aged fifty. The growth was from the middle and inferior turbinated bones. The base was curetted, and cauterized with the galvano-cautery, after several pieces had been removed with forceps. There was no recurrence eighteen months later.

C. H. Knight's case was one of extensive and rapidly recurring fibro-sarcoma of the right nasal fossa. The patient was a man forty-two years of age. There was the history of a blow on the nose twelve years before. For two years before first seen he had suffered from more or less nasal obstruction and catarrhal discharge. No hemorrhage until two months previous. He had considerable tenderness and swelling in right infra-orbital region. A soft, vascular and very sensitive mass filled the right naris. A large piece was finally removed with the cold snare from the anterior portion of the tumor, accompanied by profuse hemorrhage and great pain. This piece was reproduced with great

rapidity. Cassaignac's operation was then performed, and a mass of the growth removed with curette and wire loop, when it was found that the growth invaded the ethmoidal and sphenoidal cells, and could not be safely followed. The growth recurred rapidly, extended into the orbit, and, from the mental symptoms, probably into the brain, ending in death. No autopsy was permitted.

*Etiology.*—The information to be gathered from these cases and from those reported by Bosworth, as to the etiology, is very slight. In one of Bosworth's own cases, "the sarcoma seemed to develop after polypi had been operated on rather harshly, by means of forceps, while in Schäfer's case the same conversion had taken place, apparently spontaneously." In Heymann's case, also, rapidly recurring polypi finally became complicated by sarcoma. Taking into consideration, however, the frequency of nasal polypi (about one case for every eleven of ordinary catarrhal trouble, according to Bosworth) and the very small proportion of these cases of sarcoma in which the history of the pre-existence of polypi occurs, it seems to me rather far-fetched to attribute to them any causative relation. To be sure, frequent and rough operating on nasal polypi might tend to incite a new growth, as constant irritation is certainly a well-recognized factor in the causation of malignant growths in other parts of the body.

As Dr. Knight says, in the report of his case, the question of traumatism as a cause of malignant growth is an interesting one and, in a medico-legal light, might become an important one. While none of us, probably, believe that traumatism alone is capable of producing malignancy yet we might consider it capable of starting into activity a malignant focus. However, until we understand better the nature of malignant growths, whether starting from foci of embryonic cells or in some other way, our opinions in this respect can be hardly more than surmises. Watson says that recurring nasal fibromata show a tendency to assume a sarcomatous type. Bosworth also speaks of sarcomatous degeneration of fibromata as of not infrequent occurrence.

Out of 38 of the cases that Bosworth reports, 22 are males and 16 females. Of the six cases reported above, five are males and one female, making a total of 27 males and 17 females. As the greater exposure of men to irritating atmospheric conditions makes them more subject to catarrhal diseases, it would seem natural that the same conditions might increase their liability to malignant growths in the nose and nasopharynx, or, in other words, that catarrhal inflammation of the nose may possibly (as Bosworth suggests) predispose to sarcoma.

Of the cases in which the age is reported there were in the decades from

Age.	Cases.	Age.	Cases.
10-20 . . . .	7	50-60 . . . .	5
20-30 . . . .	5	60-70 . . . .	6
30-40 . . . .	7	70-80 . . . .	1
40-50 . . . .	15		

Of those cases occurring between forty and fifty, 11 were under forty-five. It thus appears that almost two thirds of the cases occurred in patients under forty-five years of age. In this respect sarcoma differs from carcinoma of the nasal passages, the majority of the cases of the latter disease reported being above fifty years of age. The average duration of the cases re-

ported by Bosworth was three and two-thirds years, "which would seem to show that sarcoma runs a somewhat slow course when it develops in the nose."

**Pathology.**—I will not discuss the structure of sarcoma of the nose, since it does not differ essentially from sarcoma in other parts of the body, "except in so far as it is modified by the special tissue from which it develops." Bosworth says, "It should be easily recognized by microscopical examination, and yet it must be borne in mind that the normal membrane of the nose is exceedingly rich in lymphoid tissue, which oftentimes bears a somewhat confusing resemblance to the structure of round-celled sarcoma."

**Symptomatology.**—A review of the cases reported shows, as would doubtless be expected, that the prominent, almost constant, symptom of the presence of a sarcomatous growth, as indeed of every nasal tumor, is obstruction to nasal respiration. This symptom varies with the size and position of the growth. Epistaxis is another very common symptom, which may sometimes be observed before obstruction. It is quite characteristic of sarcoma, and should make one suspect the growth to be of that nature, although hemorrhage is also common with fibroma. This hemorrhage may be due to erosion of the mucous membrane of the nose, but is probably as often due, in sarcoma, to bleeding from the tissue of the tumor itself, which is usually very friable. There is sometimes a muco-purulent discharge from the nostril affected. The growth, if of sufficient size, may cause considerable deformity.

**Diagnosis.**—The gross appearance of these growths is somewhat characteristic. The surface has usually a bluish-gray color. The consistency is usually soft and flaccid. If, with these characteristics, the growth bleeds readily and hemorrhages are repeated, the diagnosis of sarcoma is a very probable one. The color varies somewhat, according to the variety of sarcoma. In Dr. Hooper's first case the tumor is described as "a smooth, reddish" growth. In one of Bosworth's cases the growth was of a "reddish-yellow" color. Sarcoma apparently arises with about equal frequency from the septum and the turbinated bones. In the cases in which the origin of the growth is mentioned, it was the septum in eleven, the turbinated bones (one or more) in ten, in two both the septum and a turbinated and in one the floor of the nose. For a confirmation of the character of the growth a microscopic examination is, of course, always necessary.

**Prognosis.**—From the cases reported it is impossible to gain any trustworthy idea of the prognosis. In many cases the history subsequent to the operation is not given, while in many others it covers so short a period to be practically useless. In one case there was no recurrence at the end of seven years, and in two others none at the end of one year. The first of these cases we can fairly consider a cure, and probably the two others. A few months' freedom from recurrence, on the other hand, can hardly be considered satisfactory evidence of a cure. A case of sarcoma of the naso-pharynx, reported by W. H. Bennett, shows what long periods of immunity from recurrence one may see in this form of malignant growth. The first removal was in 1866, a large recurrent mass was found and removed in 1874, and another in 1890. Epistaxis was the only symptom which drew attention to the presence of the growth. During these long periods the tumor changed in character. The first consisted of fibrous tissue and spindle cells. In 1874 the cellu-

lar elements had increased. In 1890 the growth had become a typical mixed spindle-cell and myeloid sarcoma.

The above case simply enforces the injunction to see a patient from time to time for a long period after the removal of a nasal sarcoma. "Aside from these considerations, our prognosis must be based on the extent of the disease, its duration, and especially on its apparent rapidity of growth. The character of the growth has an important bearing on the prognosis, in that a round-celled sarcoma is to be regarded as more malignant in its tendencies than the other varieties. . . . In those cases where we find the sarcomatous elements intermingled with the normal tissue elements, as in fibro-sarcoma, myxo-sarcoma, adeno-sarcoma, etc., the prognosis is rendered less grave as the proportion of the normal elements increases in the tumor."

**Treatment.**—The only form of treatment applicable to a sarcomatous growth in the nose is an operative one, that is, a thorough removal of the growth by some instrumental means. The question then comes, Shall a removal be attempted, where apparently practicable, through the natural passages; or, no matter what the size of the tumor, if it be malignant, shall one of the numerous resections be performed which enable the surgeon to reach directly the seat of the growth? This is a point in which there seems to be some difference of opinion.

Ollier favors immediate resort to his operation for resection of the nasal bones, getting directly at the growth and eradicating it at once and completely. He condemns removing small portions of a malignant growth in as many sittings, believing that such a procedure exposes a patient to a much greater likelihood of recurrence. He also holds that operation through the natural passages can be, at best, only imperfectly performed, through inability to properly see and reach the parts. I can only say, in answer to this opinion, that there are certainly many cases of nasal growth where one familiar with microscopy feels competent not only "to properly see and reach the parts" but also, with the proper instruments, to remove the growth, through the natural passages.

A. F. Plicque also believes that growths of a malignant nature should always be removed by an external incision. C. H. Knight agrees with this opinion, thinking that valuable time may be lost by delay in doing this.

S. A. Fox, at the close of a report of a naso-pharyngeal carcinoma, recommends the "thorough removal from time to time with the post-nasal-curetting forceps and wire snare." He objects to the various capital operations, as being dangerous and causing more or less mutilation.

The strongest support to the practice of removing the growth piecemeal and through the natural passages is given by a case of extensive naso-pharyngeal sarcoma removed in this way by Bosworth, the operations extending over a period of more than four months. At the end of seven years there is not the slightest sign of recurrence. Bosworth says: "Ordinarily the growth should be removed through the natural passages, when it is feasible; although, if better access to the nasal cavities is demanded, an operation on the external nose does not necessarily complicate the result. The growth may be extirpated by the curette, spoon, cold snare or galvanocautery loop."

The cold snare appears to be the preferable instru-

ment, although it can undoubtedly be advantageously supplemented at times by the sharp spoon or curette. Bosworth considers cauterization of the base of the tumor oftentimes harmful, stimulating the growth to renewed activity. This was apparently true in the case just cited, for it was not until the galvano-cautery was abandoned that he made headway against the growth. For the same reason the galvano-cautery loop is not usually advisable.

"The most serious obstacle met with in these operations, is always the excessive hæmorrhage. This is probably true in all varieties of sarcoma, and especially so of the angiomatous growths. The source of the hæmorrhage is always from the tumor itself, and the indications are to get the growth out as rapidly as possible, and to get down to its attachments. When this point is reached, the hæmorrhage, as a rule, ceases at once."

As I have already said, after the primary operation, the patient must be seen at specified intervals for at least two years, to watch for any tendency to recurrence.

#### HOW IS TUBERCULOSIS ACQUIRED?

BY J. A. JEFFRIES, M.D., BOSTON.

(Continued from No. 9, page 217.)

To review the evidence as regards food, we see that tubercle bacilli are rare in flesh as sold in the markets, and that neither experiments nor observation have shown that flesh is more than a remote danger to man. Milk is an undoubted source of infection; but the results of experiments and observation on man and cattle indicate that it is not a great one.

I have ignored Brushie's argument, that human tuberculosis is due to cattle, since it only occurs where cattle are kept, for two reasons: first, doubt as to the facts; and, second, the fact that the cattle may be exempt though the people are afflicted.

Infection from dust and dirt alone remains to be considered. That tubercle bacilli are cast into our surroundings in vast numbers is self-evident. The number thrown out per annum in the sputa of the phthisical far exceeds the comprehension of man. A larger number are spit out in the sputa, and go into spittoons, on handkerchiefs, clothing, furniture, carpets and the ground. A smaller number are coughed out, often in very small particles of phlegm, and are scattered over everything in the vicinity, provided a handkerchief is not applied to the mouth, as is sometimes done. I say sometimes, for most do not practise this so-called refinement, — in reality a hygienic measure. The readiest way to satisfy one's self of size and

amount is to hold some object before the face of the cougher. I have several times, during the last few years, observed people cough before a window. The result is instructive. The same is true of sneezing, except that the particles are finely divided and almost form a spray. The result is to distribute the tubercle bacillus all about the sufferer. The same is true to a greater or lesser degree of every tuberculous lesion discharging on the surface. The bacilli escaping in human dejection go, in the great majority of cases, to places where they can do no harm. The same thing goes on with all tuberculous animals, except that the horned animals do not spit out what they cough up. Some have jumped from this to the conclusion that they do not cough out anything; this is not correct.

The dust has been chiefly studied by Cornet,<sup>42</sup> and his article is so well known that it is only necessary to state that, out of 311 trials with the dust and dirt from spaces occupied by phthisical patients 59 gave positive results. All of 77 trials made with other spaces were negative. Several other experimenters have made similar trials with similar results.

Rembold<sup>43</sup> and others have sought for and found tubercle bacilli in the air. Three methods have been used: a cover-glass with a viscous coat placed in a draught, and subsequent microscopic examination; drawing air through a cotton plug, and then putting the plug in a guinea-pig; and exposing plates with a thin layer of glycerine to the air, and then washing and using the wash-water. There is, however, a dearth of this sort of work; extended and varied research in this line is a desideratum which no private individual is liable to fill.

Spillman<sup>44</sup> and Hofman<sup>45</sup> have found that flies carry the germ in their intestines and deposit it in their droppings, and Hofman in one case out of four found the bacilli in flies' guts virulent when inoculated into the eyes of rabbits.

As might be expected tubercle bacilli have been found on the bodies of consumptives and their toilet articles.

We, therefore, know, without going any farther, that tubercle bacilli are liable to beall about us. And only two things interest us; first, How many are alive, that is, capable of infecting? and how can they get into us and our animals? A dead bacillus, or one fastened down, is of no import. When first escaping from the body many, probably most, are alive; this is proved by the extreme susceptibility of our inoculation test. The first question is, therefore, How long can they live? And to this we can safely answer, months at least. Drying, putrefaction, sunlight, are all detrimental to the plant and tend to destroy it; but none of these are prompt or sure.

Stone<sup>46</sup> has shown that the tubercle bacillus may be virulent in sputa after three years, during at least two of which it had been in a state of absolute dryness. Cadeau and Malet<sup>47</sup> found that the lungs of tuberculous cattle dried, powdered, and then exposed to the air of a room, were virulent at the end of 102 days. A piece the size of the fist, dried and exposed to the air, infected at the end of 150 days; a similar piece, buried in a three-litre flask filled with sand, was viru-

<sup>1</sup> Read before the Boston Society for Medical Observation, June 1, 1891.

lent at 159 days; also pieces in a flask of water exposed to sunlight for 120 days, and others in running water for one month, were virulent. Heim and Galtier have shown that the plant will live from one to four weeks in milk and its derivatives. It also lasts well in water (Cantamese and Vidal). It is therefore clear that, in spite of certain experiments pointing to the rapid death of the germ in the presence of putrefaction, it is quite liable to last for a long time. It must be borne in mind that all putrefaction processes are not alike.

There is therefore no doubt about the extensive distribution of the live bacillus in our dwellings; as yet it has not been found out of doors, but it must be there.

From the general dust to the interior of our bodies is but an easy transition. Every tramp of the foot, quick motion of the arm, is liable to raise a host of bacteria. The broom and feather-duster are finely adapted for raising them up; once up they may be breathed in. Tubercle bacilli are not different from others except in their rather enduring life, and we know that the air contains many germs. Besides the air the plant can gain entrance by direct contact while lying still. We touch everything, and much remains on our hands. We all know that it does not do to scatter red pepper in our rooms; it is soon in our eyes and nose. Babies are particularly bad in this respect; everything grasped goes into the mouth; and given a coming or going tooth, the opportunities for inoculation are excellent. Has this any connection with the prevalence of scrofulous glands in the neck during youth?

What we have now to consider is the evidence that such a theoretically potent factor is such in fact. Naturally we have not the number of striking observations afforded by direct infection; we cannot trace the invisible bacillus with the directness that we can infected food, and can never, so far as mechanics are concerned, be sure into which organs the plant entered. Of this the case of Toulmin already given is an illustration; where the bacilli went to, the laws of physics do not show. Those in the air probably settled along the respiratory tract, those conveyed by contact probably into the mouth, and thence either out again or into the stomach.

Besides the above I know of but one case, that of Kruche. A boy of healthy family, strong and well, occupied for a few weeks the room and bed previously used by a phthisical patient with profuse expectoration, and shortly died of miliary tuberculosis. Cattle show the same thing, it being not unusual for tuberculosis to begin with a new cow at one end of a row of cattle and travel along, stall by stall.

Cornet's<sup>45</sup> reports on the prevalence of tuberculosis among the religious orders which care for sick indicate indirect infection on a large scale. He found that for twenty-five years the average membership had been 4028.8, total deaths 2099; of these 1,320 (62.88%) from tuberculosis, and 13.94% from other parasitic diseases. These figures are not isolated; the same thing crops out in hospital records, prisons, reformatories and even barracks, in spite of the extensive out-door exercise of the troops.

Records such as that of Sendter<sup>46</sup> and Kempf<sup>47</sup> are

of significance. The former notes that on the Island of Frauen Chiensee, with a population of about three hundred souls, the deaths from tuberculosis since 1800 never exceeded seven in the decade until the last; while the cloister, with from twenty to forty members, was immune until 1860. During the sixties two died of tuberculosis; the same in the seventies; while during the last decade eleven fell victims. The latter records a convent in which a case of tuberculosis occurred in a girl of eighteen, and was followed in four months by nine more; after which the sufferers were partly put in separate rooms and isolated, partly transferred to other asylums; and the rooms cleaned, after which no more cases occurred.

The difference in the amount of tuberculosis between the single, married, and widows and widowers, is of interest in this connection. Drestree and Gallemaert's<sup>48</sup> table for Brussels, calculated to the ten thousand for each age, sex and state, is given below:

Age.	Single.		Married.		Widowers and Widows.	
	Male.	Female.	Male.	Female.	Male.	Female.
20-25.....	87.0	67.0	121.4	97.0	187.5	163.3
25-30.....	101.3	65.2	85.0	102.5	241.4	190.5
30-35.....	123.9	64.2	84.5	77.2	158.7	168.3
35-40.....	99.0	66.8	94.4	73.5	135.8	104.3
40-45.....	110.7	49.3	86.8	70.8	176.1	83.9
45-50.....	74.8	53.4	105.0	59.8	210.0	81.3
50-55.....	67.4	44.0	94.8	45.6	137.7	55.2
55-60.....	69.1	34.0	81.2	40.3	139.3	53.0
60-65.....	39.7	30.4	87.4	40.8	90.9	43.4
65-70.....	31.8	18.8	60.4	29.3	54.7	37.8
70-75.....	29.7	24.1	45.9	23.1	59.2	32.9

This table shows a greater death-rate among the married than single, and also that there is a very high death-rate from tuberculosis among the widows and widowers. The suggestion is very strong that the latter class catch the disease from their mates, and later follow them to the grave. The increase among the married is difficult to explain, since it is chiefly confined to the men. Infection from the mild and recovering cases will explain the rise in part, but apparently in part only. The bad result among widows and widowers cannot be explained by reference to the vicissitudes of this state, since it shows in both sexes, while widows alone are specially exposed to want; and this is fully counterbalanced by the want among that numerous class, the prostitutes.

Ransome's<sup>49</sup> and Flick's<sup>50</sup> figures, showing that deaths from tuberculosis tend to occur in certain houses, strongly suggest indirect infection. The same is true of the marked tendency of the disease to annihilate certain families.

As negative evidence in the same line, we have many illustrations of how care and cleanliness will cut down a high death-rate from tuberculosis, as in modern reformed prisons, or even avoid the disease. Sticks, Stiek,<sup>51</sup> in Neunberg, has had during eight

years, but one case of tuberculosis in an orphan asylum with an average of 100 inmates. The one case came in diseased and was promptly discharged as dangerous.

Objections can be raised to all these figures. Against Cornet's and similar cases it has been objected that the increased amount of tuberculosis was due, not to increased infection, but to the hardships of their conditions. No such objection can be raised where isolation has prevented farther infection, nor are the conditions of European soldiers or criminals worse during time of service or confinement than when at large.

Animals afford valuable information in many ways.

The first thing of note is the great variation in the amount of tuberculosis. While in confinement the disease may appear in any mammal, and even in snakes and other cold-blooded creatures, it is, under usual conditions, confined to domestic animals. I say nothing of hens, since it is not at all clear that hen tuberculosis is the same as human; indeed, the evidence is fairly conclusive that in most cases it is not. Many cases are recorded where hens ate sputa and later developed tuberculosis; but when we isolate and so feed them the results are negative; when inoculated the same is most always the case. And, finally, the cultures from hens are allowed to be different by no less an authority than Koch. Personally, some years ago I fed quantities of sputa to hens and pigeons, and injected it by the syringful, with no resulting tuberculosis.

Tuberculosis, though spontaneous among all domestic animals, is most common in cattle, then swine, then the others with much smaller numbers. Some speak of it as almost unknown in horses and dogs; this is not the case.

In cattle the amount of tuberculosis increases steadily with the age, and is also much influenced by sex. Thus, of 1,133,195 calves, 71 were tuberculous; of 1,958,132 grown-up cattle of all sorts, 25,163 (1.2%) were tuberculous; that is, the prevalence of tuberculosis in calves, as compared to cattle, is as 1:300. Few have given finer classifications. Goring<sup>55</sup> gives a per mille calculation, based on the reports of the inspectors of all cattle in Bavaria.

One thousand bulls . . . . .	5.84%
" bullocks . . . . .	1.34
" cows . . . . .	2.50
" heifers . . . . .	0.35
" calves . . . . .	0.09

Again, tuberculosis was distributed as follows.

Less than one year . . . . .	In 1877, 61 (1.31%)	In 1878, 65 (1.30%)
One to three years old . . . . .	328 (10.81%)	551 (12.20%)
Three to six years old . . . . .	1,816 (37.80%)	1,730 (34.50%)
Over six years old . . . . .	2,415 (50.07%)	2,360 (50.00%)

It is to be noted here that calves are those saved for cattle, and includes much older ones than those slaughtered for veal.

At Augsburg, 24,766 veal calves, with one case of tuberculosis, and 13,193 cattle, with 512 (3.95%), were slaughtered.

Strohl and Magen<sup>56</sup> give, for Munich in 1879, 1,125 cases of tuberculosis (or 2.5%), divided as follows:

Under one year . . . . .	2 or 0.2%
One to three years . . . . .	81 or 7.1
Three to six years . . . . .	378 or 33.5
Over six years . . . . .	64 or 59.2

From the *Veterinary Journal*, from the German:

11,227 oxen, with . . . . .	51 cases.
1,657 steers with . . . . .	8 "
1,389 cows, with . . . . .	45 "
598 yearlings . . . . .	3 "
30,477 calves with . . . . .	1 "

Again:

23,592 calves, with . . . . .	1 case.
8,537 oxen, with . . . . .	167 cases, or 1.94%
5,008 cows, with . . . . .	445 " or 8.88%

The figures are not very numerous, but show clearly that the increase of tuberculosis in cattle with age, as insisted upon by all European inspectors, is correct. Goring's figures have a special interest, in that the bullocks and bulls show a much higher rate than the heifers or even cows. Yet the males consume no more milk than the females, but they are kept in much closer quarters, that is much more exposed to dust infection. Sows and hogs which are kept together show no such difference. As a whole, the figures show a constant increase in tuberculosis with age, precisely what must result with a steady source of infection, and a chronic disease, and not at all the result where food during youth is the chief source of infection.

The figures of Bayard,<sup>56</sup> showing that the curves of tuberculosis in cattle and man follow each other closely all through Baden and Bavaria, are of interest. The case is cited to show the dependence of human tuberculosis on that of cattle. It would be just as reasonable to argue the other way. If men catch tuberculosis from eating the cattle, where do the cows get it from—eating each other? The proper place to look for the cause is in ways common to both, that is, indirect infection, not food.

In studying death-rates, it is to be noticed that from about the fifth to the twentieth year there is a marked diminution of the death-rate; or that there is a short high wave during the first five years; and another, with a sharp rise followed by a slow, steady increase, extending from the commencement of adult life to old age.

Some might hold that the first wave was due to infected milk, since there is some relation in time between the consumption of milk and the high death-rate. This requires a rather long step to a conclusion. The early years of life are noted for their great mortality from all sorts of causes, that is, young children are very vulnerable. During the first part of life tuberculosis spreads, becomes general with great rapidity, and immediately after develops a marked predilection for the nervous system. These are conditions peculiar to the age, not to the source of infection. The conditions of life during this period are also such as to offer very good opportunities for indirect infection. First, it is the period of closest personal contact, kissing and cosseting. Next, it is the period of life during which the head is in the sediment of the atmosphere. Young children live on the floor, older people on their feet or furniture. It is also the period of house-dwelling and bronchial troubles.

Can we conclude from the result of an autopsy, where the bacillus gained entrance to the body? There is no primary lesion as in syphilis, but is there of necessity any lesion at site of entrance? Apparently not, as shown by the numerous class of bone, joint and lymphatic tuberculosis, with healthy lungs, intestine

<sup>55</sup> Prevalence of Tuberculosis, by Lydell, Fleming and von Hertzen, *Wochschr. f. Dermatol. u. Syph.*, No. 9; *Ann. Vet. Journal*, January, 1890 and May, 1890.

<sup>56</sup> *Archiv. f. Wissenschaft u. prakt. Theierrheilk.*, xv, 89, p. 1.

and skin. Our only hope, then, is to demonstrate that the lymphatic behind the site of entrance become tuberculous, while the others do not, or at least to a much less degree, if we are to accept autopsy statistics as usually gathered. This is partly true, partly not, and least of all in regard to the glands which interest us most, those of the mesentery and the lungs. Either, indeed both, sets of glands are often attacked without their organs being affected. More in fatal tuberculosis, where the bacillus has entered through the cord, both sets of glands may form the chief lesion. In other words, the initial lesions are very apt to be concealed before death, owing to the generalization of the disease and its predilection for certain organs. Lump figures, therefore, are of little value. They show, however, two points of interest: first, in spite of all the sputa swallowed, intestinal tuberculosis is less frequent than pulmonary; second, the large amount of lymphatic tuberculosis in the young.

Though we cannot advance far with figures in the mass, still quite a number of cases justify the pathologists in selecting the point of entrance. Thus Grawitz, in 197 cases, classed 152 as primary in the lungs, nine primary in the intestines, two or three as external, and the rest as unknown. Biedert, in 1884, could only find 30 cases of primary intestinal tuberculosis reported in the literature.

The statistics from cattle killed before the disease has come to an end avoid most of the difficulties inherent in autopsies, the initial lesion is not so much hidden. Thus Goring gives the result of 1,596 cases as follows:

Lungs alone infected . . . . .	21%
Pleura and peritoneum only . . . . .	28
Pulmonary and pleural only . . . . .	39
Generalized . . . . .	9
Genital lesion only . . . . .	3

Unfortunately, I have been unable to find other similar tables; but it is evident from reading reports, that the above represent the combinations usually found. These, it will be noted, take no account of the intestine.

The cases of latent tuberculosis in man offer similar conditions to the slaughtered cattle. The disease has not spread. Where do we find these deposits? In the lungs. Kurlow<sup>67</sup> gives a table taken from the reports of several pathologists who have especially studied this subject. It is given below, with a few additions. All ordinary tuberculosis is excluded, so that the figures show the proportion of latent or cured tuberculosis in those dead of other disease.

Rogge, 100 old women. Scars in the apices of	51

These figures agree closely with the results in cattle, and clearly indicate a large mass of primary lung, that is indirect, infection.

In view of all these data, — the observations on cattle, the seat of latent tuberculosis, and the like, — it is clear that indirect infection plays a prominent part in the spread of tuberculosis. It is to be noted that the observations including large numbers all point

to this. I therefore feel justified in summarizing as follows:

It is clear that a certain amount of direct inoculation occurs.

It is highly probable that a larger amount of indirect inoculation takes place, as in skin tuberculosis, scrofula. Of this I have adduced no evidence.

Evidence is not in favor of flesh, after passing infection, being a factor of any import.

Milk is clearly a source of danger, though judging from the data at large, not a considerable one.

Indirect infection is probably the chief mode of infection, the bacilli entering through the lungs, the skin and the alimentary tract, with but few exceptions.

The application of these conclusions is very clear, the inspection of food should be kept up as at present, People keeping private cows should be taught to be cautious of those which cough, and milkers' herds should be watched. To offset indirect infection, the State should see to it that the rooms occupied by phthisical patients are properly cleansed. At the time of the millennium people may always cough on handkerchiefs, keep their hands free from sputa, and always spit into improved cups, rather than on the floor; but at present they will not. The wealthy, who have more or less followed these rules for a long time, are relatively exempt from tuberculosis.

The one sure and ready way to kill a tubercle bacillus is to cook it hard for at least fifteen minutes; antiseptics are not safe in the peoples' hands. All infected clothing should be boiled before handling, not tucked away in a bag, then shaken out, counted and washed. Everything coughed up should be spit into special cups, and thoroughly steamed before emptying and washing. Patients should not cough all over the room, but hold a handkerchief before the mouth. All rooms liable to infection should be carefully cleaned, especially the floors, furniture, and first six feet of the walls. For this we must rely on washing, outdoor beating and dusting, and antiseptic solutions. The best antiseptic is carbolic acid, the stronger the better (never less than one per cent.) applied long enough to soak in thoroughly.

At some future time people may wake up to the conditions of the case, and demand walls and floors both smooth and washable, and the banishment of the dust-traps called modern furniture, provided they do not demand a certain degree of isolation of the phthisical and the systematic destruction of all tuberculous cattle.

In closing, I would disavow all ideas of having exhausted the subject or of having demonstrated the proof of more than a few points at most. The subject is a most difficult one. We want more careful and extended studies on the occurrence of the tubercle bacilli, on the effects of administering small numbers of the same, on the probable sources of infection in individual cases, and on the course of the disease as indicative of the source and time of infection.

THE TREATMENT OF VIPER BITES. — The Paris Academy of Medicine has awarded the Orfila prize to Professor Kaufman, of the Alfort Veterinary School, for his discovery of a specific for viper bites. The treatment consists in bathing the wound with a solution of one part of chromic acid to one hundred of water.

NOURISHMENT IN ACUTE DISEASE.<sup>1</sup>

BY FRANCIS H. WILLIAMS, M.D., OF BOSTON.

THERE are few questions in the treatment of disease which have to be decided so often during the daily routine of practice as those which concern the proper support and nourishment of the patient; and, further, there are not many things connected with the care of patients which are so difficult.

It is not easy to find a person competent to prepare suitable food; it is, therefore, the more incumbent upon the physician to be able to give proper directions as to its preparation.

The chief thing is to take pains, and those who can do this are rare people, whether physicians, relatives or nurses. This is why less is accomplished than there should be in the support of the sick. If we wish to succeed in avoiding nausea, vomiting and loss of strength and even loss of life, we must learn to offer nourishment to our patients in a suitable form.

It will be my endeavor to recall to your minds a few of the principles to be kept in view in feeding patients acutely ill.

Food may be classified as follows:

- (1) Water, (2) Salts, (3) Fats, (4) Sugars (Fruits), (5) Starches, (6) Albuminoids.

The classes of foods known as starches and albuminoids are the ones which require the most care to offer to a patient in a proper form.

*Water* is of prime importance. Consider for a moment the composition of the body of a man weighing 154 pounds, as illustrated by these blocks. He is 108 pounds water, or about two thirds.

It does not follow from this that we need give every patient several pints of water a day; by no means, but it is fair to infer that water, of a suitable temperature, should not be denied the sick, and that patients too young, too delirious, or too ill to ask, should not be neglected in this regard. The physician should see to it that water is offered the thirsty economy in all cases, nature demanding it though the patient makes no request.

*Salts* are present in small proportion in most foods, and are essential constituents of our diet.

*Fats* as a rule are not tolerated by patients acutely ill, and their use should be limited to such forms as are finely divided, as in milk or yolk of egg (and even in milk it may be necessary to reduce the amount of fat by skimming off the cream).

*Common Sugar* is rapidly and perfectly changed into grape sugar and into maltose before it is assimilated.

Grape sugar and maltose are very soluble and easily absorbed, and for this reason seem a very desirable form in which to give nourishment. Horlick's and Mellin's foods are examples of preparations made up chiefly of saccharine substances.

Fruits are valuable to give variety to the diet and to contribute water, which they contain in large proportion. Most fruits contain 85 to 90 odd per cent. of water, some sugar, and the citrates, malates and tartrates of potassium. Other fruits, such as grapes and bananas, contain sugar in considerable proportion, to 20 per cent., and their value as foods is not to be despised. Among dried fruits, dates and figs contain 60 per cent. of sugar and 6 per cent. of albuminoids.

The value of certain fruits for persons who are pre-

disposed to uric acid, gravel and concretions in the bladder I shall not discuss here, though it is well worthy of attention.

Though we take foods into the stomach in the solid form, it is necessary that they be made soluble before they can be assimilated. The classes of foods which we have thus far considered are readily absorbed, namely, water, salts, fats and sugars; they are all liquid or readily soluble substances. In the remaining classes, starches and albuminoids, we have foods with which there are several steps to be gone through before they can be taken up by the system.

With all starchy foods, like grains, potatoes and rice, it is necessary to break the starch granules by heating or some other simple process, and before the starch can be absorbed it must be converted into a soluble substance, such as dextrine, which is the same in composition as starch. Starches, therefore, are not absorbed as such, but must first be rendered soluble.

Uncooked starches vary very much in the rapidity with which they may be converted into sugar by the action of the saliva. The starch of Indian corn is converted in three minutes, whereas wheat starch takes forty minutes and potato starch three hours. After thorough cooking, all starches require nearly the same time. It is, therefore, important to have starchy food well cooked before it is given to patients.

Arrow-root forms by cooking with water a mucilaginous liquid, not a pasty mass; it is, therefore, not apt to irritate the stomach and intestines. It should, however, not be used alone for more than a few days together, as it contains too little of the other constituents of a proper diet. In this it differs from rice or potato or bread, which contain gluten, salts and fats in addition to starch. Rice is better steamed than boiled, as it loses to boiling water much that is valuable. Boiled potatoes are for the same reason less nutritious than baked ones.

As regards *albuminoids*. Wholly without albuminoids, unless the disease is of short duration, the patient cannot exist. Since they are imperatively needed, they should not be omitted from the diet, even where digestion fails almost completely.

Albuminoids are complex in composition and decompose readily, and in their preparation more care is required than with any other kind of food. To avoid decomposition, they should always be fresh; and to prevent losing the albuminoids by coagulation, they should not be heated to too high a point.

To prepare meat foods properly, two things must be borne in mind. (1) Albuminoids as a rule coagulate when heated to boiling. (The casein of milk is an exception to this.) (2) To obtain a good meat flavor, the meat must be subjected to a temperature much above the coagulating point of albumen. It is, therefore, necessary to resort to two procedures, one which has for its object to extract the flavor, the other to extract the albuminoids without coagulating them.

If we treat meat with boiling water, we get beef-tea, which contains only a small percentage of solids and almost no albuminoids. This applies to all clear beef-tea. Beef-tea is of service in two ways: its taste and odor are agreeable, and together with the heat of the hot water, which acts as a stimulant, it makes a valuable article for use in the sick-room. Not as a food, but as a flavoring.

Some of the extracts of meat made with hot water may be used instead of ordinary beef-tea, thus saving

<sup>1</sup>Read before the Massachusetts Medical Society, June 10, 1891, and recommended for publication by the Society.

much time. Liebig's and probably similar extracts of beef contain no fats, gelatine or albumen. It is desirable to use only a small amount of extract, say one-third of a teaspoonful to a teacupful of hot water, as too much gives an unpleasant flavor.

Now as regards the juices of meat which contain albuminoids in solution.

From raw meat one cannot obtain as much juice as is easily expressed from the same amount of meat which has been previously heated. The reason is this: the envelope of the muscular tissue is a substance similar to gelatine, which swells and dissolves when heated, and thus after broiling the liquid portions of a steak flow out more readily. A steak when well broiled swells; if it is cooked too long, the albuminoids coagulate, it loses moisture, shrinks and becomes tough. A slightly broiled steak may be cut into square pieces, and pressed or squeezed or twisted in a piece of cotton cloth to extract the juice.

In administering beef-juice, great care should be exercised to avoid heating it to 136° F., at which point its albumen coagulates in flakes. Beef-juice, though fourteen times as rich in albuminoids as beef-tea, is so raw in flavor that it is rejected by many palates. To overcome this objection, it is only necessary to add a proper quantity of any extract of beef of good flavor to make it delicious. — about the size of an almond to an ounce of beef juice. Thus by a union of two bodies, one rich in albuminoids and the other rich in flavor, we get something that is superior to either. Beef juice is an excellent article of diet where solid food cannot be given, but it is somewhat troublesome to prepare. A pound of meat yields about four ounces of juice; it therefore costs about five cents an ounce.

Soluble albumen, such as is contained in expressed meat juice, is absorbed in the rectum to nearly the same extent as complete peptones. Albuminoids in solution are not precipitated in the stomach and afterwards dissolved, except in the instance of casein of milk, which, as already said, is first coagulated and then dissolved.

Being accustomed to prescribe meat juice, I was much pleased to find a preparation of it manufactured by a well-known firm. I hoped in this to realize all the advantages of beef juice, without its inconveniences. An analysis of this preparation which was made for me, was disappointing, as it was found to contain only one-third of one per cent. of albuminoids, compared with seven per cent. in beef juice; it had also more salt than is desirable, — twelve and one-half per cent. This is mentioned to illustrate the advantage of using foods which are prepared at home, in preference to those made by manufacturers, of which the composition is unknown. This preparation costs thirty-five cents per ounce, though it is only one-twentieth as rich in albuminoids as beef juice costing about five cents.

If one cannot conveniently get albuminoids from meat, a very nutritious broth may be made by means of hot water into which an egg has been stirred. Here we may heat three ounces of water to not above 149° F., and stir into a raw egg. The liquid is milky if we use the yolk; clear if only the white is used. It has little taste, which is an advantage with many patients, or it may be flavored with beef extract.

If one has no thermometer at hand, the temperature of the water may be determined in two ways. If the finger can be kept in the water for two seconds, or about the time it takes to count ten hurriedly, the

temperature is not too high. Liquid of this temperature is apt to burn the tongue. One hundred and forty degrees F. is as hot as one can drink a liquid, and 122° F. is a very comfortable temperature for a hot drink.

When these experiments were begun, it was feared that a temperature sufficient to coagulate albumen might be so low as to be lukewarm; but a few tests showed that any temperature which can be borne in the mouth will not coagulate albumen. (Though these two temperatures differ by only a few degrees.)

It is interesting to compare the composition of four liquids containing albuminoid constituents.

Beef tea . . . . .	about 3%
Beef Juice . . . . .	about 7%
Raw egg, with three ounces water . . . . .	about 5% albumen, 6% fats
Milk . . . . .	4% albumen, 4% fats, 4% sugar

In all of these we get a good proportion of salts.

It may happen that the digestive organs cannot tolerate eggs, or, more especially, milk. But by means of powders which contain pancreatic ferments, such as Fairchild's peptonizing powders, milk may have its albumen converted into albuminoids, which do not coagulate by heat, and into diffusible albuminoids or peptones. In the ordinary process of peptonizing milk, both of these bodies are formed, but the proportion of peptones is small.

In the case of milk, which forms solid curds in the stomach, a partial conversion of its casein into albuminoids which do not coagulate, has obvious advantages. Peptonized milk is so well known that I hesitate to do more than mention it to you; on the other hand, it is so useful a preparation that I will say a few words about it for the sake of such practitioners as may not appreciate its value, especially as there are a few precautions necessary to its successful use. The powder is put in a quart bottle, with a little water, milk is added and the whole is placed in a vessel of water about as warm as the hand. The process of partial digestion goes on while the milk is at this temperature; boiling stops it, cold delays it and preserves it. If the digestion is continued in this way for twenty minutes or more, the milk has a bitter taste. If this taste is objected to by the patient, the time may be shortened to five minutes or even less, in which case, however, the amount of artificial digestion is small. If the milk is to be given by the rectum, the digestion may be kept up for two hours; in this case the milk does not curdle when acids are added to it. About four quarts of peptonized milk will support a person in health.<sup>2</sup> For a patient in bed, less than this is sufficient, the amount varying with each individual.

Milk treated in this way contains albumoses and some peptones. For our purposes, we may broadly define albumoses and peptones as soluble albuminoids, which cannot be coagulated by heat or dilute acids; and peptones have the further property of passing through the membrane of a dialyser, and represent a later state of digestion. Even after prolonged digestion, we get in peptonized milk only a small amount of peptones, the casein being converted chiefly into albumoses.

The bitter taste of peptonized milk is not thoroughly understood; albumen and albumoses are tasteless, and peptones have a cheesy taste.

Meat albuminoids are converted by the stomach into bodies which are soluble or diffusible, and these substances when artificially produced have been regarded

<sup>2</sup> Horton-Smith: Journal of Physiology, April, 1891.

as calculated to render great service in invalid feeding.

It is known that an increased secretion of urea appears after the administration of peptones, just as it does after the ingestion of unaltered albumen, and that the chemical composition of peptones differs little from that of ordinary albuminous bodies. They have the manifest advantage of being easily and immediately absorbed. Peptones, so far as we yet know, may be used during short periods of extreme exhaustion, when perhaps few other albuminoids could be assimilated.

Many preparations have been offered for sale which purport to be peptones, but which really contain only a small amount of them. Many such preparations are soluble in water, but have a very disagreeable odor and unpleasant taste.

So much in outline for the various classes of foods.

Since acute disease is accompanied by fever, we must consider the effect of feeding in cases where the temperature is febrile in character; also, the amount of food, its quality and quantity, together with other conditions affecting its absorption.

In acute disease accompanied by fever, what are the conditions? The body loses weight, the urea especially is increased, and carbonic acid and water are excreted in larger amount than in health. All of this loss is not dangerous if allowed to go on for a few days only, and if the amount does not exceed certain limits.

But to replace these losses we are at a disadvantage as regards the ability of the system to assimilate food. In fevers, the appetite is small, or may be completely lost. The saliva, the gastric juice, the pancreatic fluid, the bile, are less efficient in action, or are diminished in amount during high temperature. The stomach is very sensitive, in part perhaps through sympathy with the increased sensitiveness of the nervous system as a whole. If there is much hyperæsthesia of the digestive tract, as in typhoid, in peritonitis, in dysentery or gastro-enteritis, one must be careful not to give too much food, and it should be in liquid form.

It is not, however, the administration of food, but the administration of unsuitable food, that we have to fear, and also the giving of nourishment in quantities unsuited to the digestive powers of the patient.

One should not give the patient what he cannot digest, nor should we give him less than he can assimilate. The attendant must have a constant watch over the condition of the patient's powers of digestion, and carefully adapt his food to his capabilities, especially during convalescence.

Our attention should be devoted not only to what is put into the alimentary canal, but also to what goes out. For example, if curds of undigested milk are found in the stools of a typhoid patient, the quantity of milk should be diminished, or it should be diluted.

Large quantities of milk are often given to typhoid fever patients, to their great detriment, and excess of zeal in feeding and too little care in the preparation of the food, cause much of the intestinal trouble that complicates these cases. In diphtheria, foods which are soft in consistency, rather than liquids, may be used, as they are less apt to get into the trachea.

Every careful observer of the sick will agree that many patients are starved in the midst of plenty, simply from the want of attention to the ways which come make it possible for them to take food. For example, if the patient has a fever with remissions or

intermissions, it is of the first importance to remember that the ability to digest food at these times is greater, and the more nourishing portions of the diet should be given during the remissions and intermissions.

As far as practicable, the mouth should be kept clean. The tongue may become cracked and dry; it may stick to the sides of the mouth, and cause so much pain when the attempt is made to swallow, that the patient refuses food which he would otherwise take. The mouth should be rinsed with water after taking food, and should be carefully cleansed with an antiseptic solution from time to time. In a word, for extreme cases, the important thing is liquid food. We should give water. We should give sugars (starches have no taste, but are less readily absorbed). Fats are not tolerated. Salts are present in nearly all foods. We should give albuminoids, in beef juice, in peptonized milk. Ordinary milk becomes solid in the stomach.

The physician should never lose sight of the patient's likes and dislikes; one cannot diet a patient from a book, or from the chemical composition of foods. On the other hand, it is incumbent upon the physician to know how to choose such a variety in diet as to include both what is palatable and what will afford a proper amount of nourishment.

It has been one of the aims of this paper to show that the preparation of some valuable foods is entirely in our own hands, and that we need not be dependent upon manufactured preparations, of whose composition we are often ignorant; and further, to emphasize many details concerning the nourishment of patients which, though well-known and often repeated, are also too often overlooked.<sup>3</sup>

## Medical Progress.

### RECENT PROGRESS IN OBSTETRICS.

BY CHARLES M. GREEN, M.D.

#### THE INFLUENCE OF MENSTRUATION ON LACTATION.

THERE is no question of practical importance on which the opinions of physicians differ more widely than that of whether or not the reëstablishment of menstruation should preclude the continuance of nursing. Schlieter<sup>1</sup> (Vienna) has endeavored to settle this question by a series of investigations in the new Austrian Foundling Asylum.

In order to know surely the influence of menstruation on lactation, it is necessary, first, to prove in a number of cases whether nursing children manifest any changes on the reëstablishment of menstruation in the nurse, and, if so, of what nature. To determine this point, in a series of fifty-two cases, the suckling was weighed before, during, and immediately after, the menstrual epoch, and averages prepared of the results before, during, and after the period, and, when possible, at later times: the appearance of the dejections and the general condition of the infants were also examined and recorded. Secondly, the nurse's

<sup>1</sup> Wiener Klin. Wochenschrift; abstract in Centralblatt für Gynäkologie, 1891, No. 2.

<sup>2</sup> Among other authors, I am indebted to Munk & Uffelmann, to Ruge's Physiological Chemistry, and to the recent books on Food by Church & Vesey, and especially to Mrs. Richards, instructor in Sanitary Chemistry, in the Massachusetts Institute of Technology, who kindly made the analysis of beef juice.

milk was analyzed in thirty-three cases, in order to determine whether any present condition of dyspepsia or intestinal catarrh in the infant could be attributed to changes in the milk due to menstruation, or whether the infant's condition was accidentally coincident with the nurse's menstrual period. Schlicter found that there was an increase in weight from day to day during menstruation, in the case of many children a considerable gain. Taking the averages there was a marked gain in weight during and after the period over that before the period, and a persistence of this increase, though to a less extent, in the later time. The general condition of the nurslings during menstruation was entirely satisfactory. The milk analysis gave, on the average, less differences between the milk during and after menstruation, than between the morning, noon and evening milk of one and the same non-menstruating nurse. The author therefore concluded that menstruation in itself exerted no unfavorable influence on the development of the infant; and that if there were any apparent disturbances in the infant's condition, they should be attributed to the neglect and want of care on the part of the nurse, attendant on the malaise of the menstrual molimen.

Schlicter groups his conclusions as follows:

(1) After the sixth week post partum returning menstruation of the nurse is injurious to neither mother nor child.

(2) Menstruation or hemorrhages before the sixth week may possibly retard the development of the child.

(3) Illnesses of the infant arising during its nurse's menstruation, like dyspepsia, colic or intestinal catarrh, are to be regarded as accidental coincidences, and accordingly are to be treated, not *a priori* by changing the nurse, but as ordinarily, by the usual methods.

#### HYPEREMESIS GRAVIDARUM.

Kaltenbach<sup>2</sup> (Halle) has read a valuable paper on this subject, excluding from consideration all complicating affections that excite vomiting in the non-pregnant state. In hyperemesis of pregnancy in its narrower sense, post-mortem appearances in the sexual and digestive organs are negative or non-characteristic. Uncontrollable vomiting of the pregnant, like the lighter forms of this affection, is, in his opinion, of nervous origin. The excessive increase of the symptom is not to be ascribed to definite pathological changes in stomach or uterus, but to a peculiar condition of the nervous system, in which reflex irritability is increased and reflex inhibition is diminished: in short, it results from a functional neurosis,—from hysteria. In a case observed two years ago, in the Halle clinic, an extremely hysterical gravida was cured of her vomiting from day to day by a simple daily washing-out of the stomach, after it had been suggested to her that now the cause of her sickness had been removed, and she was destined to vomit no more. Since that time further conclusive cases had been reported to the reader. The reference of hyperemesis to hysteria clears up many hitherto dark points in the etiology of the affection,—the inexplicable sudden cessation of the vomiting in consequence of any psychical or somatic influence.

Anomalies of uterus and stomach have only the significance of favoring causes in addition to the neu-

rosis. Should further observation prove the frequent or constant connection of hyperemesis with hysteria, our therapeutic ideas must be thereby greatly influenced. We shall be more reluctant to resort to artificial abortion than heretofore. We shall treat the fundamental neurosis, and especially seek to impress the patient psychically. Already good results have been obtained with anti-hysterical measures. Frequently the patient will have to be removed from unfavorable surroundings in order to be treated successfully.

#### HEREDITARY DURATION OF LABOR.

Anvard (Paris) has reported<sup>3</sup> seven cases in which the length of the labors of the daughters surprisingly resembled that of their mothers, the daughters being very much like their mothers in every respect. On the other hand, he has observed cases in which women resembled their fathers, where the duration of labor was like that of the father's mother. Anvard naturally restricts his remarks to such women only as have no impediments in labor peculiar to themselves.

[Such observations have no especial practical value, but they are not without interest; and the making of them may serve to relieve the tedium of ordinary obstetric practice among those who have the almost bygone opportunity of attending both mothers and daughters in their hours of greatest need.]

#### PROGNOSIS AND TREATMENT OF PUERPERAL ECLAMPSIA.

Löhlein (Giessen), read a paper<sup>4</sup> on this subject before the German Society for Gynecology at Bonn, May, 1891, based on the material of all the great German clinics. In 52,328 cases of labor, eclampsia was observed in 325, the proportion being one in 161; the highest ratio occurred in the Charité, one in 67; in the three great Vienna clinics the rate was one in 318. If all the cases transferred to the various clinics in a state of eclampsia are excluded from consideration, convulsions occur in the German clinics among those who come under observation by admission before labor (as is customary in many foreign clinics) once in 330 cases. This proportion is higher, however, than is usually accepted; the commonly received ratio being 1:500, as given by Scauzoni and Schröder, and accepted by Lusk.

Of the 325 cases, 63 died of eclampsia and 14 of other complications; excluding the latter cases, the mortality from eclampsia was only 19.38%, an indication of great progress in the treatment of this most serious class of cases, in which the usually accepted mortality is at least 33%. The lowest mortality found by Löhlein, 11.6%, was in primipare in whom eclampsia first appeared post-partum; the highest, 29.4%, in multipare who were seized before labor began. If the cases fatal by complications are included in the death-rate, the mortality reaches 23.63%,—still a very favorable showing. The fetal mortality is not given.

Among the sequelæ, which were noted in the 248 survivors, were observed 13 cases of pronounced psychoses, most of which fully recovered; five pneumonias, three pleurisies, and 22 cases in which there were lasting affections of the kidneys.

Operative interference was necessary in 71.1% of

<sup>2</sup> Arch. de Toecologie, 1888, No. 9; abstract in Centralblatt für Gynäkologie, 1891, No. 20.

<sup>4</sup> Centralblatt für Gynäkologie, 1891, No. 23.

<sup>1</sup> Centralblatt für Gynäkologie, 1890, No. 49.

the cases, to wit, — 108 forceps operations, 19 versions, 13 destructive operations, and seven Cesarean sections: of the latter five were on the dead, one on the moribund, and one on the living, — the last with favorable result for mother and child.

As regards medicinal treatment, Löhlein and numbers of others, acting on the warm recommendation of G. Veit, in 1887, had employed by preference large doses of morphia. In eight clinics in which the morphia treatment was used, the maternal mortality was only 13.8% against the general average 19.38%.

#### THE MANAGEMENT OF OCCIPITO-POSTERIOR POSITIONS.

Zinke (Cincinnati) has an interesting paper<sup>5</sup> embodying the report of a case of what he believes to have been a primary occipito-sacral, or what the older writers classify as a sixth, position. Traction with forceps completely extended the head, and it was born as a face by flexion without laceration of the soft parts.

Primary occipito-sacral positions are of rare occurrence, and by many writers are believed never to occur: Madame Boivin is credited with having seen two cases; Naegele and Meigs each two, and Dewees three. Certainly such cases are of such rarity as to make it inexpedient to cumber obstetric nomenclature with a classification of them among the usual positions. Whether primary or secondary the management of all posterior positions of the occiput is essentially the same: intelligent and skilful effort must be invoked to promote anterior rotation; and failing this, the head must be extracted as nearly as possible in a condition of perfect flexion to secure the engagement at the outlet of a favorable diameter, or else the head should be completely extended and delivered as a face, as was done in Zinke's case.

In his remarks on the general management of occipito-posterior positions, Zinke gives prominence to one expedient, which, although known and practised by many, is not, it is believed, thoroughly appreciated. When it is evident that anterior rotation will not take place, and the head has become arrested, Zinke recommends introducing the hand into the vagina under complete anaesthesia, seizing the head and rotating into an O. L. A. or O. D. A. position, according to its original engagement, and holding it there until it is fixed in its new position. This procedure has never failed in Zinke's hands, and it has served the reporter well in a number of cases. To insure success in this manipulation, however, the reporter has found it important to promote simultaneously, the anterior rotation of the child's body also, either with the disengaged hand or with the aid of an assistant, by external taxis through the abdominal wall.

Blanc (Lyons) published<sup>6</sup> in 1887 three cases, and later two cases, in which manual rotation of the persisting posterior occiput was successful. Subsequently he reported<sup>7</sup> two cases in which, although manual rotation was accomplished without difficulty, the head returned to its former position when released by the hand. In both these cases the pelvis was faulty, — in the one case funnel-shaped, in the other a simple flat: possibly, Blanc did not, in these cases, secure by external manipulation anterior rotation of the body. At

all events manual rotation is almost always successful and is unattended with danger in skilful hands.

#### STATISTICS OF TWIN LABOR.

Brém (Budapest) has reported<sup>8</sup> some interesting statistics concerning multiple pregnancy and labor, based on 10,000 labors occurring in Kézsmáry's clinic from 1869 to 1887. In the 10,000 cases were 127 cases of twin labor and three of triplets, — twins occurring once in 78 cases, and triplets once in 3,333. Of 252 twins, 133 were boys and 119 girls, the ratio of boys to girls 111.76 to 100, being somewhat higher than in single births. In 37% of the cases the children were of opposite sex; in 34% both were boys; and in 28% both were girls: these relations agree with Lusk's statistics. Of the mothers, 25% were primiparae, and 75% multiparae. In 51% of the cases there were two separate placentae, and in 26% the two originally separate placentae were united at their proximate borders: in both of these classes there were two chorions and two amnions, which must in each case have developed from two distinct ova. In 23% there was a single placenta (one chorion and two amnions) which must have developed in each instance from a single ovum with a double germ. In one case, which according to present knowledge, must have sprung from a doubled-yolked, single ovum, — a single placenta with freely anastomosing vessels — there was droscopy of one amnion, and scanty fluid in the other; the child in the former sac being normal, while that in the latter was an acardiacus.

Of 248 twins the presentations were: Head in 67.74%, breech in 29.43%, shoulder in 2.83%.

The relative positions are shown in the following table, with a comparison of Spiegelberg's statistics, which latter were based on over a thousand cases:

	Brém.	Spiegelberg.
Both heads presenting . . . . .	47.58%	49.06%
Head and breech . . . . .	35.47	31.70
Both pelvic presentations . . . . .	11.29	8.60
Head and transverse . . . . .	4.83	6.18
Breech and transverse . . . . .	0.80	4.14
Both transverse . . . . .	0	6.33

The commonly accepted opinion that the larger twin is usually born first is not borne out by Brém's statistics, since in over 43% of his cases the smaller child came first. In Spiegelberg's experience the larger twin was usually born last.

In Brém's cases labor was normal in 75%; in 25% there was operative interference with one or both children. The length of the labor in primiparae was on the average, 21 hours 55 minutes, as against 15 hours 52 minutes in single labors in the same clinic. In multiparous twin labor the average duration was 11 hours 42 minutes, against 11 hours 8 minutes in average single labors.

The interval between the births of twins was less than one hour in 83.04% of the cases, from one to six hours in 12.50% of the cases, more than six hours in 4.46% of the cases.

The practice in this clinic differs from the teaching of Kleinwächter, who taught that the second twin should be delivered, artificially if need be, immediately after the birth of the first. In Kézsmáry's clinic the second twin is interfered with only in the direct interest of mother or child; and the maternal mortality in 127 twin labors was 4.72%, as against 13.11% in 61

<sup>5</sup> *Amer. Journal of Obstetrics*, January, 1891.

<sup>6</sup> *Yvon Medical*, 1887, Nos. 3, 4, and 5.

<sup>7</sup> *Archiv für Gynäk.*, 1888, abstract in *Centralblatt für Gynäk.*, 1891, No. 26.

<sup>8</sup> *Oryginal Berthap*, 1890, Nos. 42-47; *Centralblatt für Gynäkologie*, 1891, No. 8.

cases of Kleinwächter's. The latter, however, lost a somewhat smaller per cent. of the children. [In regard to interference with the second twin, the writer pointed out ten years ago in a paper on twin-labor, that an important duty of the obstetrician, after the birth of the first twin, was to *prevent a malposition of the second*, for the reason that malpositions of the second twin are almost always secondary. If such malpositions are prevented, or promptly rectified before an improper engagement of the second twin, operative interference with the second child will be seldom necessary.]

Simultaneous entrance of both children into the pelvis occurred in only one case, in which the chin of the first child, born by the breech, became locked on the head of the second. [To avoid this possible misfortune, it would seem to be good treatment to prevent the engagement of a first-coming breech by pushing it aside and securing the descent of the other child when it presents the head.] Prolapse of an arm occurred eight times; prolapse of the cord, four times; placenta prævia, once; eclampsia, three times; post-partum, atonic hæmorrhage occurred in one-sixth of the cases. [This is a danger always to be watched for and guarded against in twin labors, owing to the relaxed and over-stretched condition of the uterine walls.]

The average length and weight of the children was 18.4 inches and five pounds six ounces, respectively. The twins were non-viable in 15.74% of the cases, premature in 15.74%, and mature in 68.50%. The maternal mortality was, as previously mentioned, 4.72%; the morbidity, 33.3%; while in single births in this clinic the mortality and morbidity amounted to 1.16% and 27.1% respectively.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT.

#### SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MAY 20, 1891, Meeting called to order by the Secretary at 8 p. m. The Chairman being absent, on motion Dr. W. H. HASTINGS was chosen Chairman *pro tem*.

The first paper was read by Dr. J. PAYSON CLARK, upon

#### SARCOMA OF THE NOSE, WITH REPORT OF A CASE.<sup>1</sup>

DR. CHEEVER, in opening the discussion, said: The paper of Dr. Clark is very complete and very interesting. I was not aware that so few cases of this affection had been reported. What I have done generally for these affections has been by surgical methods. So far as my experience goes, I do not agree with the reader in relation to recurrence; at least in regard to innocent growths becoming malignant. In the present manner of treating these growths, we possess distinct advantages over former methods of treatment. In the old time operations in the nose we were brutal in the extreme. Forceps were introduced into the nasal orifice, and without light, and without sight, everything was removed which could be obtained. I have

never myself seen a change in the nature of the growth from simple polypus to sarcoma. I have operated for recurrence of naso-pharyngeal fibromata, and the second operation has usually been final. This is not true of the sarcomatous growths. Operation in this class of tumor may relieve the disease and prolong life, but a recurrence is almost certain to occur. I remember a case occurring in the practice of Dr. March, of Albany, in which I operated no less than five times for sarcoma, within the space of five years, with the effect doubtless of prolonging life, and rendering the patient more comfortable though the disease was not eradicated. The operation for removal of abnormal growths in the nose may be done in several different ways. One of these is by means of an incision along the border of the ala of the nose, thereby separating the wing of the nostril from the cheek, and lifting it away from the face, by which a greatly enlarged opening is secured for reaching the interior of the nasal cavity. This does not destroy the septum, and the contour of the nose is in no way affected. The wound heals rapidly and perfectly, and no disfigurement is apparent.

For the higher growths the operation proposed by Ollier is undoubtedly the best. In this operation the nose is divided from its attachment to the bones of the face by sawing through the tissues at the root of the nose, and when all the bony structures have been divided the nose is attached only by the cartilages and soft tissues at its lower end. The body of the nose is then drawn away from the face, and thus exposes a large opening high up, by means of which access may be had to all parts of its interior. The resulting deformity is almost nothing, and in this photograph of a patient thus operated upon, there is no apparent cicatrix from the operation. The form and shape of the nose are undisturbed by the operation. Ollier's operation gives access to the antrum and the pharynx and to the higher parts of the nasal cavity, and the turbinated and ethmoid bones are accessible. In an operation I devised, the naso-pharyngeal spaces are reached by sawing the superior maxilla transversely, and replacing it. In another operation it is proposed to separate the two lateral halves of the superior maxillary bone and thus to reach the seat of the growth through the mouth. Nelaton devised a method of reaching certain portions of the pharyngeal and nasal cavities by dividing the soft palate, and thus exposing a large portion of the posterior nasal space. I have no reason to think that cauterization has a tendency to provoke renewed growth in these tumors.

I recently treated an old man for disease of this kind, by the use of caustics, but did not obtain so good a result as by the curette. This was followed by the application of fuming nitric acid, and subsequently by an application of potash. In the case reported by the reader, the patient will probably need further operation. It will become necessary to open the face, and thus gain a larger opening through which to reach the seat of the pathological growth, and secure its entire obliteration.

My views are rather conservative in regard to the operations for removal of growths about the face, and are at variance with the opinions of some other distinguished surgeons. Some time ago I had a controversy in the pages of the medical press with Dr. Sands, of New York, who advocated the entire removal of all the soft parts of the bones which were in any way

<sup>1</sup> See page 239 of the Journal.

affected by the presence of a foreign growth in the cavity of the nose. I do not think that so extensive mutilation of these structures is always justifiable or necessary.

DR. C. F. FOLSOM read a paper upon

#### SOME POINTS REGARDING GENERAL PARALYSIS.<sup>2</sup>

DR. FITZ was expected to open the discussion, but was not present.

DR. C. IRVING FISHER presented a report for the Committee appointed by this Section in reference to the Social and Statute Recognition of Syphilis,<sup>3</sup> and stated that he was able to inform the Society that their Committee had not been idle. The action of the Committee has been this:

(1.) To bring the subject before the Massachusetts Medical Society upon the occasion of its last annual meeting.

(2.) To present the importance of this matter to the attention of the different District Medical Societies in the Commonwealth. Blank petitions were sent to all the different societies, which were filled out and presented at the State House. The committee laid the subject before the Homœopathic Medical Society, and the members of that Society took an active part in urging the necessity of the passage of the measure which the committee represented.

(3.) The committee were granted a hearing before the Committee on Public Health of the Commonwealth, who reported unanimously in its favor. Some senator objected to the bill as unconstitutional; whereupon the Committee changed the bill so as to make its application relate first to paupers, which bill it is hoped may pass. Another bill provides that if a prisoner is sick at the end of his term of imprisonment, he shall be retained under supervision until his disease is no longer dangerous to himself or others. This bill is in the hands of the Judicial Committee at the State House. There has been a great deal of interest in the passage of the bill among the members of the legislative bodies, and all are convinced that such a bill should pass. Public opinion has been to a considerable extent aroused upon the subject, and a degree of interest awakened never before known in relation to the care of patients with syphilis.

DR. C. F. FOLSOM said that it is not generally known that there was an effort at one time to care for patients with syphilis by means of the Public Charitable Institution upon Rainsford Island. From this fact the hospital upon this island became to all intents and purposes a syphilitic hospital, and was generally known as such. The nature of the disease for which it was used became so notorious, that when the girls who had been treated there were returned to the city, they would not infrequently be met upon the dock on the arrival of the steamer, and be conveyed to their destination in a barouche, with the utmost attention upon the part of their male admirers. At length it became necessary to suspend the reception of this class of patients in the hospital, and since this time there is no place in this city where such patients can be received for care and treatment. At the same time, it was strongly felt by the public that something ought to be done to secure some degree of immunity from the disease, and the matter was placed in the hands of the Judiciary Committee of the State. It was decided

that the attempt to restrain persons suffering from this disease within the house of detention or the almshouses or prisons of the State would be unconstitutional, and the subject never reached the stage of application. In Tewksbury, a court was established for the trial of prisoners, but when the patients with syphilis became aware that they might be detained on account of disease, the number of admissions with this disease became markedly less, and many of the patients in the institution would jump the fence and thus make their escape. The women could not do this so well, and only occasionally made their escape.

The fate of this attempt at law-control of syphilis is interesting. The politicians at the State House had many friends and constituents who had syphilis. One of these legislators undertook to get the law repealed, and after a time succeeded by means of the introduction of a bill to that effect, which came up at a time when few friends of the original bill were present, and the repeal was effected.

In England the Lock Hospitals have done much to diminish the dangers to the public from syphilis. These institutions are generally misunderstood by the public, who imagine that they are hospital-prisons, in which persons with venereal diseases are confined until they may be cured of their disease. This is not true, the hospitals were founded by Mr. Lock, M.P., and residence in them is entirely voluntary upon the part of the patients. They do a great work in the care of patients who would otherwise have no treatment for these affections.

DR. MASON; In bringing this subject before the Society it is believed that some good may be accomplished in the formation of public opinion and in the statement of the fact that there is no ward or other place of similar character in the city of Boston, with a population of 400,000 souls, in which cases of syphilis can be received and cared for. Probably no city of the world is so poorly provided with facilities for the reception of cases of this and allied diseases as is Boston. Legislative enactment in the premises does not promise much at present.

DR. FISHER stated that there is at present considerable interest among the members of the Legislature in relation to state control of syphilis, and he is frequently consulted in regard to measures for its restriction.

DR. V. Y. BOWDITCH for the Committee appointed by this Society made a report upon

#### THE CONDITION OF THE STREETS OF BOSTON.

As the result of a paper read at one of the meetings of this body by Dr. Langmaid, a committee consisting of Drs. Bowditch, Knight and J. C. Warren was appointed to take action on behalf of the Society. That committee has had repeated consultations with two mayors, the boards of aldermen and with the governor. Certain results have already been obtained, and the work will be pressed as thoroughly as possible. Within a few days the committee are to meet the board of Police Commissioners and still further advocate the need of clean streets. Dr. H. J. Barnes has also been indefatigable in the same direction, and has aided the labors of the committee. It is necessary that individual as well as combined effort should be made to accomplish the end desired. In New York, Dr. Loomis has been engaged in the same work, where gratifying results are promised in the near future.

<sup>1</sup> See page 196 of the Journal.

<sup>2</sup> See Journal, vol. xxxiii, p. 110.

DR. HAROLD WILLIAMS exhibited samples of a new preparation for the

TREATMENT OF DISEASES OF THE THROAT AND PHARYNX

in young or refractory patients in whom antiseptic applications to the throat become necessary. The desired articles are incorporated in the form of a compressed tablet, which is flavored with peppermint, and has no appreciable taste of the antiseptic substances contained in the tablet. Those shown to the Society were made of salicylic acid, corrosive sublimate, borax, etc.; and in no sample was there any disagreeable taste. They are prepared from formulæ of Dr. Williams, by Wyeth & Co.

## Recent Literature.

*Hypnotisme et Croyances Anciennes.* Par le DR. L. R. REGNIER. 8vo, pp. xxiii, 223. With forty-six illustrations and four plates. Paris: Aux Bureaux du Progrès Médical. 1891.

The idea is current that hypnotism dates back to a rather remote antiquity; that it has been practised by the Hindoos for centuries and that it was not unknown in Egypt and Greece. The object of the present work is to study carefully the history of hypnotism, and to see how far the current idea is correct. That natural somnambulism must have existed from all antiquity must be admitted. The physiological and pathological conditions have varied so little within recorded time that such conditions must necessarily have arisen, just as we know that ecstasy, hysteria and similar morbid conditions have arisen in all ages. The question is, however, whether a somnambulism artificially produced, with unconsciousness on waking, that is,—a true hypnotism,—was known at a remote period. The author begins his study, therefore, with the sacred books of India, and then considers the magic of the Chaldees and the Hebrews, the temple-healing, and the various practices of oracles and sibyls among the Greeks and Romans, and studies with care the practice of sorcery and the magic art of the Middle Ages. He finds in the Upanishads the first record in the directions for producing states of ecstasy, but here he finds that the ecstatic preserved a complete memory of his hallucinations. The dreams of the patients in the Greek temples of healing were spontaneous, and the patients often had to wait many nights before they came; but, although the priests employed these dreams and other suggestions to influence the imagination of the patients, they never put the patients into a hypnotic state and gave them true hypnotic suggestions. In like manner, in all the trance conditions and hysterical outbursts of the Middle Ages, there is no evidence of artificially-produced sleep, and no record of somnambulant states with oblivion on waking. "There were certainly hypnotizable individuals, who perhaps fell asleep themselves, or were put to sleep by chance; but, if there were such persons, there were no hypnotizers who knew how to provoke sleep artificially and to utilize it for various ends." In the sixteenth century various doctrines concerning animal magnetism began to arise, inaugurated by Paracelsus, and developed by Kircher, Maxwell and others. This led,

finally, to the doctrines maintained by Mesmer. To Puységur, however, we owe the discovery of artificial somnambulism, which, as is well known, was first put on a scientific basis by Braid. In the concluding chapter the writer gives a brief review of the modern scientific study of hypnotism from Braid to Charcot, and he inclines rather to the doctrines of the school of La Salpêtrière than to those of the school of Nancy. In conclusion he gives the result of his own researches on the circulation in four hypnotized patients, which shows that there is probably in the hypnotic state a condition of cerebral congestion. Such being the case, these repeated congestions and the excessive functioning to which the brain is exposed in hypnosis may lead to definite troubles of nutrition and permanent alterations in the brain. He therefore takes a definite stand against public exhibitions, and is a firm believer in the possible dangers that may arise.

The book is an interesting and careful study, and is a valuable contribution to the history of hypnotism.

*The Psychic Life of Micro-Organisms: A Study in Experimental Psychology.* By ALFRED BINET. Translated from the French, by THOMAS MCCORMACK, with a preface by the author, written especially for the American edition. 8vo, pp. xii, 120. Chicago: The Open Court Publishing Company. 1889.

A little book representing one of the first systematic efforts to differentiate "psychic life," or "vitalism," from the harder facts of physiological chemistry. The subjects treated are of such intense interest, and at the same time of such extreme complexity, that it would hardly be possible to conceive of their being settled after one discussion; and that end has certainly not been here accomplished. Few will be found to deny that there may be found some elements of true psychic energy in the lowest organisms with which we are yet acquainted, but our knowledge is as yet so elementary that convincing arguments to that effect are exceedingly difficult to come at. There is certainly vast room for investigation in this direction, the lines for which are but just beginning to be indicated. H. C. E.

*The Micro-Organisms of the Human Mouth: The Local and General Diseases which are Caused by Them.* By WILLOUGHBY E. MILLER, D. D. S., M. D., Professor at the University of Berlin. With 128 illustrations, one Chromo-Lithographic, and two Photo-Micrographic Plates. 8vo, p. xxii, 364. Philadelphia. The S. S. White Dental Mfg. Co. 1890.

The first edition of Dr. Miller's admirable work in German was published in 1889; and the book before us is a translation of the same, with certain enlargements and additions in the way of illustrations. It is the most complete of which we have any knowledge, in the special line of which it treats, and must be an invaluable aid to any one who wishes either to investigate the same subject, or to know what has been done already in this direction.

A certain amount of knowledge of the processes set up by the various forms of bacteria found in the mouth is a matter of necessity to every well-educated dental surgeon, and nowhere can this knowledge be better obtained than in the book here spoken of.

## TUBERCULOSIS IN ALL ITS RELATIONS.

At the recent International Congress in London a combined meeting was held of the Sections on Bacteriology and on the Relations of Diseases of Animals to those of Man, for the purpose of discussing tuberculosis in all its relations. The subject was opened by Prof. Burdon Sanderson, with a short address, stating concisely the questions before the meeting and his own attitude in regard to them.

He was followed by Dr. Bang of Copenhagen, Professor Arloing of Paris, McFadyen and Woodhead of England, Hamilton of Aberdeen, Nocard of Paris, Hime of Bradford, Barlow of London, and Perroncito of Italy.

Dr. Sanderson put the subjects for discussion before the meeting in the following manner:

"(1) Does general tuberculosis in man originate from intestinal infection? (2) If it does, is it possible to guard against so fearful a danger?"

"The first of these questions is pathological, for it concerns the mode of origin of the disease itself; the other is practical, for it has to do with the use we can make of whatever pathological knowledge we may possess for the protection of the community.

"For the purpose of avoiding useless discussion on subjects on which there ought to be perfect agreement of opinion, I will ask you to accept certain fundamental propositions as settled, such as, for example, the existence of a *mycobacterium morbi* in the form of the tubercle bacillus, its constant association with the tuberculous process, and the identity of human with bovine tubercle.

"I would ask you also to allow it to be assumed that any part of the body of a tuberculous animal, or any secretion of such an animal, would, if it contained tubercle bacilli, be a source of danger, and that the use of such liquid or part ought to be prohibited or avoided. This being understood, we are in a position to enter without further introduction on the questions which require answers, some of which are pathological, or, if you prefer it, etiological, the others practical or administrative. The etiological questions relate to the three possible ways in which a human being may be infected by tubercle, namely, inheritance, pulmonary inhalation (atmospheric infection), and food (enteric infection). The practical issues are—(1) Is the risk to the individual consumer of such a nature that it can be detected and estimated? (2) Is it of such a nature that it can be counteracted? (3) Is the collective risk to which the community is exposed sufficient to demand the interference of the State? and (4) if it is, how can the State interfere with effect? I do not

propose to discuss all of these questions myself, but I commend them to the attention of the Congress as questions which require discussion."

Dr. Sanderson's own views in regard to these questions, after being elaborated somewhat in detail, were finally expressed in the form of the following propositions:

"There is no sufficient reason for supposing that in the human adult the introduction of the bacilli of tubercle by enteric absorption is the efficient cause of tuberculosis. In infancy a large proportion of the apparently idiopathic tuberculous diseases of the lymphatic system are probably due to the penetration of bacilli into the organism from the intestine; but the evidence which we at present possess on this subject is not sufficiently precise or extended to serve as a basis for prophylactic action. For this reason the origin of tuberculosis in infancy is a subject which urgently requires investigation.

"It has been proved that the ingestion of any material which contains the bacilli of tubercle is a source of risk to the consumer, but the conditions which limit this risk are insufficiently known. It would therefore be unjust to enforce the destruction of any specimen of meat apparently healthy, even though it were known to be derived from a tuberculous animal, excepting on evidence given by an expert as regards the particular case that it would be infecting if administered to test animals.

"As regards the duty of the State in relation to the prevention of tuberculosis, what is immediately required is, first, that tuberculosis should be added to the list of diseases regarded by the law as contagious; and, secondly, that an efficient system of skilled inspection should be created. This is desirable, not merely as a first step towards the prevention of the sale and consumption of tuberculous meat, but as an indispensable means of acquiring better information than now exists. To be of use, it must be carried out on the principles I have already set forth. It must be conducted by men of technical skill, acting under scientific guidance."

In regard to milk, he expressed the conviction that the consumption of unboiled milk during the years which follow weaning, must have its share in bringing about the fatal prevalence of tuberculous disease at that period of life, a prevalence represented by the estimate that about forty per cent. of the children who die in the hospital die tuberculous.

Of those taking part in the discussion all, except Professor Arloing, agreed essentially with Dr. Burdon Sanderson. Professor Bang concludes from careful observation and experiment in Sweden, that the seizure of all tuberculous animals is too stringent a measure; if the tuberculosis is strictly localized, the meat is not a source of danger—flesh itself not containing tubercles, although muscle-juice does occasionally contain bacilli. Where the disease is generalized, eating the meat may be dangerous, although it is not always so. The eating of uncooked meat should be discouraged, but the best means of avoiding danger to the health of man is to take all possible measures for preventing the propagation of tuberculosis amongst domestic animals.

With respect to milk, the question of prophylaxis was easily settled if it were resolved never to use it without its first being boiled. This, however, would not do for the products of milk, such as butter, cheese, cream cheese, butter-milk, etc., all of which may contain tubercle bacilli retaining their vitality for periods of from fourteen to thirty days. A separation of the cream by the centrifugal machine separates the bacilli to a large extent, but not entirely, from the milk nor

even from the cream. Bang thinks that in a certain, perhaps small, proportion of cases the milk from phthisical cows whose mammary gland is unaffected is dangerous.

Drs. M'Fadyean and Woodhead maintained that the evidence as to the transmission of tuberculosis through the flesh or milk of tuberculous animals was very conflicting, apparently in great part because the methods used were different and the conditions not uniform. Their own experiments and investigations had led them to conclude that there was great necessity for the thorough inspection of both dairy cattle and of animals slaughtered for food purposes; but the danger from milk was greater than that from meat, and only in a certain proportion (undetermined) of cattle affected with tuberculosis did there seem to be any danger from eating the flesh. There is not yet sufficient evidence on which to decide that the total seizure of meat from tuberculous animals should be resorted to.

Nocard, of Paris, took the same position, whilst also admitting that the ingestion of tuberculous material, whether in meat or in milk, was attended with much greater danger for children than for adults.

Professor Arloing, on the other hand, still adheres to the view which he enunciated at the Paris Congress of 1888. Whilst admitting that the "*diagnose précoce*" of tuberculosis in animals is very difficult, and also that *careful* cooking under public supervision would render affected milk and meat innocuous, he, nevertheless, still maintains that total confiscation of tuberculous meat is the safest method to be adopted. In the first place, however, a system of strict inspection should be instituted, not only in large towns, but also in smaller centres of population.

At the suggestion of Dr. Sanderson, in order to obtain further light upon the invasion of the system by tuberculosis, it was resolved that at the next congress the same sections should discuss the etiology of tuberculous disease of infancy and early childhood, between the ages of three months and five years.

The difficulties attending legislation for the inspection of meat are clearly and concisely put by Dr. Sanderson in his preliminary paper, and apply with at least as much force here as in England, though perhaps being less applicable to the continent of Europe. He says:

"The practical result to which we have come is this. Everything turns on diagnosis. The legislature might direct that all meat intended for consumption should be subjected to inspection, might appoint inspectors, impose penalties, and provide just and adequate compensation, but all this would be of no use unless the principles on which the discrimination of infecting from non-infecting meat is to be founded, could be laid down, and the services of skilled persons of sufficient intelligence to apply them could be secured. We may consider it quite certain that in this country, at least, it would at present be extremely difficult to find such persons. . . . Two things, in short, are required, neither of which we have at our disposal—special scientific knowledge and technical skill. In my judgment the former must be acquired first. Science must determine, much more definitely than has been done as yet, what are the earliest changes which have their seat in the parts of animals used for food, and which of these indicate danger to the consumer. This

knowledge can only be acquired by experiments specially made for the purpose. Having been attained, it can only be applied by technically trained persons. I cannot better illustrate the sort of skill required than by comparing it to that possessed by the professional tea-taster as regards the commercial value of tea. I believe I am right in stating that the gustatory judgment of the tea-taster is so implicitly relied on that the largest transactions are regulated according to it. Why is the judgment of the expert reliable? It is because he is responsible for it and paid for it. It would be the same as regards the early recognition of tubercle in cattle if skill and discrimination were paid for; and the moment that this skill is required it will come into existence. What is wanted in the inspector is not that he should be a pathologist, or even a bacteriologist, but a trained expert; for although the rules unconsciously used by him may be based on scientific principles, it is not by these principles he is guided in each case, but by practical skill."

Whatever interest we allow ourselves to take in this question of inspection and confiscation of food products, we must not lose light of the fact, which was emphasized by several participants in this debate, that the majority of tuberculous infections arise from man himself; and the elimination of the possible sources of infection from man to man should, therefore, not cease to occupy our primary attention.

The article, published in this and the last issue of the JOURNAL, by Dr. Jeffries, under the title of "How is tuberculosis acquired?" will be found of especial interest in connection with this discussion at the Congress, and from it a pretty full bibliography of the subject may be obtained.

#### THE PRESENT ESTIMATION OF TUBERCULIN.

THE present opinion of Koch himself as to the value of tuberculin formed the basis of some remarks by Professor Ehrlich at the recent Congress of Hygiene and Demography. He followed immediately after a joint paper by Drs. Metschnikoff and Roux, on the changes that took place around the tissues of tubercle bacilli, in which they indicated the difference in the reaction of tissues to tubercle bacilli when the disease was going to run a favorable course and when the animal was going to succumb to the disease. The process of recovery consisted of concentric rings of hard and inflammatory tissue around the bacilli, which eventually led to their absorption, the inflammatory tissue itself finally undergoing a process of calcification.

It is the promotion of this process, according to Ehrlich, which must be sought for in the use of tuberculin. The original opinion, that necrosis of the tubercular tissue, and consequent discharge of the bacilli, as seen after the injection of tuberculin, was desirable, that is, curative, had been shown to be erroneous, in fact, this necrosis was distinctly harmful, and to be carefully avoided. He said that the results obtained were exceedingly favorable, and that most of those in which he had failed to obtain equally good results had failed because he had used too large doses of the tuberculin. The principle of cure rested in the local effects which tuberculin exercised on the specifically affected tissues: slight and often rapid stimuli

would give rise to cicatrization of the tuberculous centres, so that the essence of this method of treatment was to retain as long as possible the specific excitation of the tissues and not to do away with these, as was the case where large doses were used. Whenever successful results had been obtained, they had all been got by the use of repeated minute doses of tuberculin, which was only very gradually increased in strength. It should be specially noted that the pathological signs found as the result of the action of tuberculin were always produced by large doses.

The opinion expressed by others present, on the value of tuberculin, did not seem to be as hopeful as Ehrlich's. Professor Cornil and Drs. Bardach and Ponfick were agreed that tuberculin was a heroic and dangerous remedy, about which we as yet knew little, and which was therefore still in the experimental stage. It also seemed to be the general opinion that there was danger of setting up generalization of a tuberculosis that had hitherto been localized. As the results of his own experiments, Dr. Hunter had succeeded in isolating principles quite different from those mentioned by Koch. They were three: Those which produced fever but set up no local reaction; those which gave a local reaction, but no fever, and those which set up neither fever nor local reaction, but which had a distinct remedial effect.

In summing up, Sir Joseph Lister hoped that in time we should all be able to obtain the wonderfully satisfactory results that had been described by Professor Ehrlich on Dr. Koch's behalf.

#### MEDICAL NOTES.

**TYPHOID FEVER IN NEWARK.**—A serious outbreak of typhoid fever is reported from Newark, N. J. Both aqueduct and well-water is used for drinking purposes, and there appears to be much difference of opinion as to which is mostly at fault. The lowest sewers of Passaic empty into the Passaic River only four miles above the spot where the Newark water mains are supplied.

**HEALTH PUBLICATIONS IN FRENCH.**—The Maine State Board of Health has printed a French edition of its circulars on diphtheria and scarlet fever, for the benefit of the residents of the State who read French more easily than they do English.

**INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.**—The permanent International Committee has appointed the following International Subcommittee to prepare a scheme for the organization of future Congresses: Professor Brouardel, (France), Professor Dr. Fodor, (Hungary), and Professor Corfield (England), to represent Hygiene; and M. Korosi (Hungary) and Dr. Janssens (Belgium), to represent Demography.

**THE NEW INSTITUTE FOR INFECTIOUS DISEASES,** at Berlin, was formally opened on Monday, August

17th, in the presence of Professor Koch and his assistants. The first six patients, all suffering from disease of the lungs, were admitted the same evening. The head of the clinical department is Professor Brieger; that of the scientific department the well-known hygienist, Dr. Pfeiffer. Drs. Petruschky, Frosch, and Behring are among the assistants. The attendants in the clinical department are "Maerkische Schwestern" (Brandenburg Sisters), who devote themselves solely to the care of the sick without any special religious bias.

**SYSTEMATIC BEGGING.**—The business of begging is better organized in Paris than in American cities, says the *Popular Science Monthly*. A large association exists there, calling itself the Paris Syndicate of Professional Mendicants. The managing committee assign posts to its members, protects them from competition, collects their receipts once or twice a day, and pays each one his proportion of the general profits once a week. The proper income of each post is accurately known, and any "embezzlement" is quickly detected and punished. A certain percentage of the receipts is retained for the general expenses of the syndicate and for a reserve fund. A lodging-house has been bought with this fund, and the remainder is invested in shares and bonds. There is no sick or burial fund—the sick are best able to excite charity, and when they become actually disabled there are the free hospitals; while the funerals of the poor are paid for by the State. Why should the professional mendicants waste their money on these things, when the tax-payers will provide them? The alleys in the Champs-Élysées are good posts for picturesque-looking old men. On a good day such should collect from thirty to forty francs each—six to eight dollars. One veteran used to get as his share of the division over seventeen dollars a week. He has now retired. The better class of mendicants look forward to saving enough to buy a cottage in the country, and living thereafter on an annuity, while the good-for-nothings spend their income in sottish debauchery. The Municipal Council, after an investigation, recently decided to tolerate the existence of the syndicate.

#### BOSTON AND NEW ENGLAND.

**DR. O. W. HOLMES** celebrated his eighty-third birthday on Saturday last. During the summer, we are glad to know, Dr. Holmes has been in remarkably good health and spirits.

**THE DEATH OF DR. G. H. LYMAN.**—The immediate cause of the death of Dr. George H. Lyman, which occurred in London on the 19th ult., as reported in our last issue, was, we understand, from an attack of facial erysipelas, of which he had had a previous attack in this country some years ago. He was just seventy-two years of age.

**A NEW HOSPITAL ON LONG ISLAND.**—The City architect has completed plans for a new cottage hospital on Long Island, Boston Harbor. The administra-

tive building will have an area of 44 by 47 feet and a height of probably three stories. It will contain the hospital offices, nurses' and matron's rooms, and the usual conveniences of the administrative department of a hospital. The ward building will connect with the main building by a corridor. This building will extend 140 feet in a north and south direction. The plans provide for the addition of two more long wards whenever occasion requires them. The present expenditures will be in the neighborhood of \$50,000. The hospital is for women, and at the size contemplated by the present appropriations, will accommodate about one hundred patients.

**MEASLES AT QUARANTINE.** — The British steamer *Kansas*, of the Warren line, arrived at Boston last week with two hundred steerage passengers. During the voyage there were five cases of measles on board, but all had recovered at the time of the steamer's arrival. As a precaution against further outbreak fourteen passengers were sent to quarantine, at Gallop's Island.

**MARLBOROUGH HOSPITAL.** — The trustees of the Marlborough Hospital have purchased a building for \$5,000, and will commence at once to remodel it for a temporary hospital.

### Miscellany.

#### OBSTETRICAL SOCIETY OF BOSTON. RESOLUTIONS ON THE DEATH OF DR. GEORGE H. LYMAN.

CHARLES W. TOWNSEND, M.D., SECRETARY.

At a Special Meeting held August 28, 1891, in commemoration of Dr. G. H. Lyman, the following resolutions were adopted:

The members of the Society desire to place on record their sense of the loss occasioned by the death of their late associate, Dr. G. H. Lyman. As our former president he was faithful in his efforts for its welfare and advancement. As a member, his contributions to its proceedings added much to the interest and value of our meetings. His interesting and valuable historical sketch of its members in the War of the Rebellion is a faithful record of the services of those of us who were privileged to aid, in field or hospital, in the great struggle for the preservation of the Union and the extinction of slavery in our land.

The Society respectfully offers to the family of Dr. Lyman its sympathy in the bereavement they have sustained by his death.

(Signed) F. MINOT, }  
S. L. ARBET, } Committee.  
C. W. TOWNSEND, }

Remarks were made by Drs. Minot, J. Stedman and J. G. Blake, on the life and character of the deceased, and a letter on the same subject from Dr. C. E. Stedman was read.

#### THE MEDICAL BUREAU OF THE COLUMBIAN EXPOSITION.

This very necessary adjunct to the great fair was organized June 1, 1891. Staff: Jno. E. Owens, M.D.,

Medical Director; W. H. Allport, N. R. Yeager, S. C. Plummer, Assistant Surgeons.

The Bureau took charge of medical, surgical, and sanitary inspection work on the grounds July 1, 1891, and is now in active operation.

A temporary dispensary and emergency hospital has been constructed, where medical and surgical attendance and medicines are furnished to employes during the day free of charge.

The Bureau is amply equipped with instruments, medicines, operating-room furniture, stretchers, cots, and an orderly. The City Police Department has furnished a patrol wagon for ambulance service to be used until a permanent ambulance has been constructed, and the Exposition Company provides horses, harness and driver.

The present Bureau operating during the construction period will be the nucleus of the medical service of the World's Fair. It is the intention of the Medical Director to make the records of the Bureau as complete as possible from a statistical and historical standpoint, and to furnish at the close of the service a report which will be valuable in the organizations of the Medical Bureaus of future Expositions.

Present number of persons living or working on the grounds is 2,000, increasing weekly. Several accidents have already occurred, and the Bureau has had ample opportunity to demonstrate its right to existence.

#### THE SENSE OF TASTE IN THE LARYNX.<sup>1</sup>
